# PREFACE

---

The *Encyclopedia of Food and Culture* is all about food: a single authoritative source about the most essential element of daily life. Here you will find articles by food historians, anthropologists, chefs and bakers, nutritionists and dieticians, farmers, agronomists and horticulturists, food stylists, and specialists in the culinary arts. In developing the *Encyclopedia*, the editors took special care to make the content interesting and the organization useful for those who want to learn about a particular topic, to make the text enjoyable for those who simply want to explore the wide and wonderful world of food, and to provide sufficient authority and depth for researchers. If this *Encyclopedia* does not tell you everything you need to know about food, it will show you where to find it.

The articles are arranged in alphabetical order, but the overall work was conceived thematically to ensure treatment of all essential aspects of food (see the Systematic Outline at the back of Volume 3). For example, the *Encyclopedia* covers staple foods, such as fruit, fish, meat, and vegetables; cooked and processed foods; food production, storage, distribution, preparation, and processing; and nutrition and constituents of food, such as fats, minerals, starch, and sugar. You will also find articles on festivals and feasts and on major countries and regions of the world, on world religions and their food customs, and on people who have been influential in food history. If a topic does not appear in the table of contents, look in the index; there will likely be several mentions of the subject in different articles. In the *Encyclopedia* you will find the topics you would normally expect in a book about food—such as bread and cheese, cooking, and vitamins—but you will also find some surprises, as in the articles on “Cannibalism,” “Pet Pigs of New Guinea,” “Seabirds and Their Eggs,” “Disgust,” and “Poisoning,” as well as “Spam” and “How to Read an Old (Handwritten) Recipe.” The *Encyclopedia* covers human history from Stone Age nutrition to the future of food, and it reaches all around the world—geographically and culturally—from Australian Aborigines and the Inuit peoples to Pacific Ocean societies and the Inca empire; from the Japanese tea ceremony to food as a weapon of war. Each article concludes with a bibliography and cross-references pointing readers to topics of related interest. The articles are generously illustrated with many rarely seen photographs, line drawings, and old advertisements, and are supplemented by maps, tables, and informative sidebars. Each volume contains a beautiful eight-page color insert of images selected by Associate Editor William Woys Weaver.

Entries explore what constitutes food, how it is procured, where it originates, and what is in the foods we eat. You will find detailed accounts of the

production of food, including fishing, hunting and gathering, and types of agriculture as they relate to ecological and environmental considerations, and you will be introduced to some of the unusual foods that are consumed around the world. You can also read about what is done to food once it is procured, including preparation and processing, distribution, storage (such as ancient and modern preservatives), food preparatory rituals (religious and secular), and the science and technology underlying food processing (including the chemistry and physics of food preparation and processing).

In a larger context, the *Encyclopedia* enables readers to trace the ways in which food affects our lives both nutritionally and socially, across the boundaries of time and place, throughout many cultures and their traditions. The articles cover the nutrition and biochemistry of food, food science, various conditions and health disorders associated with food, dietetics, constituents of food, the pharmacological effects of foods, and the physiology of eating, digestion, and nutrition.

The editors are aware, however, that people eat food and not nutrition. For most of us, food customs and preferences are influenced by social determinants that are deeply rooted in cultural values and historic traditions. The next time you eat, ask yourself, Why this food and not some other? What does this food reveal about me socially, culturally, and physiologically? Where did its ingredients come from? Why were these ingredients and not others included in the food? Does it contain any additives I should know about? As even a casual reader will note, the food we eat does not begin and end on our plates: how and when we eat, what we eat, and where and with whom we eat—all these choices display a range of behaviors about food that define and symbolize who we are. Hence, the *Encyclopedia* documents the act of eating from the perspectives of cultural history, nutrition, ethnicity, religion, psychology, anthropology, geography, economics, and aesthetics. Further, food-related behaviors are considered for their symbolic and cultural meanings, as in the entries about religion, holidays, table manners, social class, gender, sexuality, taboos, the arts, magic, and mythology.

In order to cover important cultural dimensions of food, the editors looked for experts who could discuss ethnic and national traditions across multiple disciplines and regions of the world and, where possible, provide an integrative approach to the dietary traditions of a people, nation, or region. Entries on countries with great food traditions that have had worldwide influence, such as France, Italy, and China, give attention to the foods and typical diets of the various regions of these countries, both historically and culturally, and consider important social, religious, political, economic, migration, and environmental factors.

The editors sought the contributions of authorities in a variety of fields in order to consider food from many perspectives. For instance, a chef might look at the artful arrangement of food on the plate or how it sears in a hot pan or grill. But a nutritionist is more interested in how the nutrients in a food may be affected by what the chef did to the food during preparation, what kinds of fats were added to the searing pan, or what nutrients may have been lost or altered during cooking. A food scientist may focus on the degree to which the food was safer to eat after it was heated to such a high temperature in the pan.

Authors were urged to try, within the limits of the allotted space, to write as comprehensively about their topic as possible. For example, the entry for chocolate covers the botany, history, and archaeology of cacao (chocolate bean), the principal ingredient of chocolate, and gives detailed consideration to how chocolate is produced and procured, stored, transported, and processed into various forms to be used in foods like candy and confections. The author also covers chocolate's cultural aspects, from its Mayan origin to its diffusion to the royal courts of Europe, and explains the technical discoveries that led to its commercialization and widespread availability.

The contributors give attention to the geographic origins of many foods and include their diffusion around the world and through time. Food history entries span the human evolutionary time scale, through prehistoric, ancient, and more recent periods for well-known societies and civilizations. Contemporary topics include food politics, genetic engineering, water as a resource, food supply and food shortages, advertising and marketing, the restaurant industry (including fast foods), and the commodification of various food traditions.

We believe that the *Encyclopedia* addresses a serious need for an integrated information source that encourages a greater appreciation of food, its history, and its ethnic diversity, while also explaining its nutritional significance. It is by combining a wide range of perspectives—a collaborative effort of hundreds of specialists—that this source can provide answers to many questions about health, food policy, hunger, food studies, and the food industry, while at the same time enhancing appreciation for the wonderful variety and history of the foods we eat.

We hope that by providing an integrative approach to food, nutrition, and culture over time and throughout the many regions of the world, this *Encyclopedia* will stimulate new insights about human evolution, adaptation, and creativity, and a richer appreciation of the many meanings of food and culture in our everyday lives.

**ACCEPTANCE AND REJECTION.** Foods vary along a hedonic dimension, that is, in their ability to evoke pleasure. A food's hedonic value can differ significantly between individuals and among cultures. In developed countries at least, pleasure is probably the strongest determinant of diet. For most of us, most of the time, a global emotional response to the taste of a food determines whether it is consumed. Underlying this seemingly simple decision is a remarkable range of emotions—from blissful appreciation of haute cuisine to a profound rejection elicited by feelings of disgust. As with many other complex human behaviors, the development of food likes and dislikes reflects the operation of multiple influences—genetic inheritance, maternal diet, child raising practices, learning, cognition, and culture. In fact, the development of food preferences may be an ideal model of the interplay of these influences during our life span.

Foods may be selected or rejected for a variety of reasons, including their anticipated effects on health, their perceived ethical or environmental appropriateness, or practical considerations as price, availability, and convenience. However, it is our responses to the sensory properties of a food—its odor, taste, flavor, and texture—that provide the underlying basis of food acceptance. This article will focus on some of the influences that shape hedonic responses to foods, their flavors, and other sensory qualities.

### **Tastes**

Despite evidence of innate hedonic responses to basic tastes, the vast majority of specific food likes and dislikes are not predetermined—no one is born liking blue cheese, for example. This is not to suggest that basic sensory qualities are unimportant. On the contrary, relatively fixed hedonic responses to sweet, salty, bitter, and umami (glutamate taste) tastes, and almost certainly fat, are present at or shortly after birth, and continue to exert an influence on food preferences. The strong affinity that children show for very sweet foods, and the persistence of the early development of liking for the taste of salt and salty foods throughout life appear to be universal. A majority in many Western societies also choose a diet that is high in fat.

However, innate responses do not account for the broad range of food likes and dislikes that develop beyond infancy. For instance, humans and many other mammals can detect bitterness at low levels and find it unpalatable because it is a potential sign of toxicity. Yet, while coffee and beer are typically rejected on first tasting, they are ultimately the strongest contenders for being the global beverages. The pungency of spicy foods is also initially rejected. Worldwide, though, chili is second only to salt as a food spice. Thus, although innate influences are clearly important in food selection, these are modified by our experience with foods (although both physiological makeup and culture will partly determine the extent to which experience is allowed to operate). What is more important than our innate preferences is the fact that we are predisposed to learn to like (and sometimes, dislike) foods. Some other preferences do appear to be common across cultures whose diets are very different. However, examples such as the widespread liking for vanilla and chocolate flavor are likely to reflect some degree of common experience.

### **Texture**

Texture is a crucial criterion for sensory acceptance and rejection. Certain textures do seem to be universally liked, crispness, for example—perhaps through its association with freshness. Of course, to some extent, we will always prefer textures that are compatible with our dentition, and thus we would not expect infants to like hard foods. Foods that are difficult to manipulate in the mouth—such as soggy foods—are commonly disliked, as are foods that require excessive saliva and effort to swallow, such as dry, tough meat. While food texture is often cited as a reason for rejecting food, for example raw oysters, it is likely that such preferences are also a function of our prior expectations for specific foods.

### **Color**

Food color is also undoubtedly a strong influence on acceptability, but again this is likely to reflect prior expectations. Whether we prefer white (U.S.) or yellow (U.K.) butter depends on what we have eaten in the past. Some colors have been thought to be inappropriate for food. The color blue, for instance, has been suggested as a candidate for a universally inappropriate food color—after

all, very few foods are naturally blue. But recent marketing of brightly and “inappropriately” colored foods for children tends to undermine this notion, since the children appear receptive to unusual colors. Removing color from common foods does reliably reduce liking for those foods, perhaps by undermining our ability to identify their flavor, thus making them seem less familiar.

### **Fear of the New**

The fact that humans are omnivores creates a paradox. On the one hand, we have access to a large range of potential nutrients; conversely (in nature at least), we are much more likely to be exposed to toxic substances. In the first two to three years of our lives, we exist in a highly protected environment, first in the context of breast or bottle feeding, and then through parental food selection and supervision. It is therefore adaptive for young infants to accept a wide variety of foods as the risk of exposure to potentially toxic nonfoods is low.

In later infancy, greater independence is typical, both in terms of the wider variety of other people encountered and also of the potential to come into contact with edible substances, which may be unsuitable for health or other reasons, outside direct parental influence. At this point, food neophobia often becomes apparent. Reluctance to consume novel foods at this age is most obviously reflected in statements of “I don’t like it” to foods that have never been tried. The rejection of unfamiliar foods can now be seen as adaptive, given the wider risk of ingestion of potentially toxic substances. Food neophobia is found not just in humans, but also in a variety of non-human species, including rats, dogs, birds, and fish. Hence, it may be a universal safeguard against potential toxics.

The trait of food neophobia has been investigated in different age groups, as has the nature of the “fear” and how it can be modified. Even in adults, there often remain strong vestiges of childhood neophobia. While many welcome the chance to sample exotic foods or novel flavors, others remain unable to even consider consumption of foods beyond their usual repertoire.

Such reluctance is especially strong for foods of animal origin (unfamiliar meats, dairy products, or eggs), the same foods that elicit reactions of disgust, also thought to be a protective mechanism. Why this food-related personality trait varies so much among adults is unclear, but it might reflect the breadth of experience with different foods in childhood.

Interestingly, in both children and adults, food neophobia appears to be mediated less by any conscious awareness of the potential for danger, than by the much more immediate fear that foods will taste unpleasant. Consistent with this, willingness to try a novel food can be increased by strategies that reduce this anxiety, including providing information about the food’s flavor or indicating that others have enjoyed it since. Highly neophobic individuals are more likely to choose an unfamil-

iar food after they have seen others select it. Specific nutritional information (such as the fact that a food is low in fat) also encourages selection of novel foods, but only for those for whom nutrition is important. In each case, the net effect is to assure the taster that the food is acceptable in terms of flavor and perhaps safety. Neophobia is a major issue for many parents concerned about the narrow range of foods that their children are willing to consume. A common strategy is to use one food as a reward for eating another food—one that the adult wants the child to eat. Unfortunately, these attempts frequently fail because the relative value of the foods is quite apparent. Rewarding the consumption of spinach by giving ice cream presents a message simple enough for any young child: ice cream is a good food (at least in terms of taste), otherwise why use it as a reward; spinach is bad, else why do I need to be rewarded for eating it? The unfortunate, if predictable, consequences of such strategies are increased liking for the reward and a decrease in liking for the target food.

### **Learning to Like**

What does reduce neophobia and encourage consumption? In both children and adults, repeated exposure has been found to lead to increased acceptability of novel foods, with greater exposure producing greater liking. For example, three- and four-year-old children have been found to accept initially rejected cheese and fruits following ten exposures. It is possible that individuals who receive repeated exposure to a wide variety of foods as infants and children are least likely to be highly neophobic as adults, although this has yet to be established. That is, the more we experience different foods, the more we are willing to experience different foods.

Exposure appears to be the one mechanism that is necessary for liking to increase. With novel foods or flavors, repeated consumption might lead to increased liking via a reduction in neophobia—effectively a relief from the anxiety associated with novelty. It certainly produces an increase in familiarity, an important aspect of children’s likes and dislikes, and it has been recognized for some time that sensations of recognition are in themselves positive. However, changes in liking for food ingredients or ingredient levels in already familiar foods strongly suggest that exposure per se produces liking, and that a food or flavor does not need to be completely novel. There are many commonplace examples of this, including the gradual increase in liking that accompanies changing from regular to low-fat milk or low-salt soup, or reducing sugar in tea or coffee.

Although it is a necessary precondition, by itself, exposure is insufficient to explain why we end up liking some foods more than others. There appears to be a variety of other processes that operate during repeated food experiences, producing preferences for the diverse range of food odors and flavors that we encounter. Whether sniffed as aromas, or as characteristic flavor qualities in

the mouth, food odors reliably inform us whether we have previously experienced a food. Odors are thus most likely to be the source of neophobic responses. However, there is nothing intrinsic to the odor or flavor of any food that means we will develop a strong like or dislike for it. During our early infancy (up to about three years old), we appear to be neutral to most if not all odors, except for those that also produce nasal irritation, such as ammonia. In contrast to those for tastes, odor preferences are almost certainly all learned, and rely upon our ability to form associations with other liked qualities. Pairing a novel flavor with a sweet taste, for example, reliably increases subsequent liking for that flavor, even when the sweetness is not present. This process, known as classical conditioning or associative learning, was first described scientifically by Ivan Pavlov. He famously demonstrated that the sound of a bell, previously associated with the presentation of food, would elicit gastric secretions in his dogs. While the principles of Pavlovian conditioning were developed using animal (especially rat) models, they appear equally applicable to explaining aspects of human food likes and dislikes.

The universal high palatability of sweetness and fat is a reflection of the ability of substances associated with these qualities to provide energy to the body. Our bodies find the provision of energy inherently rewarding. Consequently, repeatedly pairing flavors with ingested carbohydrates or fats produces increases in liking for associated flavors. Other postingestional consequences have also been described, including enhanced liking for flavors paired with the alerting effects of caffeine—a plausible mechanism, together with the energy provided by the sugar and milk fat sometimes added, for the enormous popularity of coffee.

The effects of conditioning by positive association and the absorption of energy-rich foods are broad enough mechanisms to account for very many food likes. One implication of this process and the body's response to energy is that we end up showing a liking for foods that are high in sugar and fat. Clearly, this has implications for health. We may know that high-fat foods present us with a risk in the long term, but what drives our behavior primarily is the fact that we like the fat—it gives the food a pleasant mouthfeel, it carries flavor well, and it provides the body with energy. The body's response is to promote liking for flavor associated with the fat. Eventually, it is not just the fat or sugar content that we find palatable, but the specific flavor of the food as well.

Food dislikes may also result from Pavlovian conditioning. Associating a characteristic food flavor with nausea, as sometimes occurs with food poisoning or a coincidental illness, will promote a rapid, often irreversible, "taste" aversion that actually seems to make the flavor become unpleasant. The development of aversions can be seen as highly adaptive—it makes sense to avoid foods previously associated with gastric illness. Consequently, the conditioned association tends to be very

This sequence of pictures shows the reactions of babies from four to ten hours old prior to experiencing food of any sort. The left column shows their natural response to the sweetness of sucrose placed on the tongue, while the right column shows their response to the bitterness of quinine. Their facial expressions resemble those of adults tested for the same responses.

strong. In humans, taste aversions are typically both long lasting and robust enough to persist even if it is known that the food was not the source of the illness. As with neophobic responses, meat seems to be a common target when aversions do occur. An unfortunate consequence of the nausea associated with cancer chemotherapy is the development of taste aversions. Close to three-quarters of children aged two to fifteen years old undergoing treatment are reported to have at least one aversion. Taste aversions are not common enough to account for the majority of our food dislikes, since they appear to occur in only about 30 percent of people. However, they are a powerful indicator of the role that consequences of food ingestion can play in shaping our responses to a food's sensory qualities.

Odors are not the only sensory qualities in foods for which preferences are shaped by learning. Our most primitive sense is the detection of pain—unsurprisingly,

## CRAVINGS FOR FOOD

At some time, most of us have experienced a craving for a specific food—something that we must have now, and which we will go out of our way to obtain. It is almost as if the body is insisting that we must have that food. There is much anecdotal information about craving and physiological needs, but less hard evidence for such specific appetites. It is clear that we get hungry and thirsty, but does the body really crave particular nutrients?

The one incontrovertible specific hunger that humans possess is for sodium chloride, common salt. Salt is metabolically essential and most of the time this need is both met and exceeded through diet. Clinical studies have demonstrated that in cases where the body is depleted of salt, humans develop strong appetites for the taste of salt, and its normal degree of palatability is increased. The same is true in experiments in which volunteers are fed low-salt diets—salty foods increase in palatability. Hence, it appears that a change in the hedonic value of the taste of salt is the mediator for increased intake when depleted.

Beyond salt appetite, however, there is little strong evidence that other specific appetites exist. There are reports suggesting an association between pica (the consumption of earth) and mineral (especially iron) deficiency. This practice appears to be most prevalent among pregnant women in poor rural communities. Pregnancy is well known to be associated with craving for foods, but it is not clear whether such “normal” cravings are related to metabolic needs.

The single most commonly craved food in Western societies is chocolate. Although chocolate contains pharmacologically active compounds, there is no evidence these compounds are what is craved. Instead, the craving for chocolate is related to craving sweet foods generally and to chocolate’s palatability, based on an optimal combination of sugar and fat. Chocolate craving is more common among women, and hormonal influences have been suggested as being important. The craving shows a peak around the time of menstruation and is also more common during pregnancy. While chocolate and sweet food cravings do occur among males, cravings for savory foods are more common.

A less extreme version of craving is the phenomenon of “moreishness.” Again, wanting “just one more bite” appears to reflect the high palatability of certain foods, rather than a desire for any specific nutrient. Foods described as moreish also tend to be consumed in small amounts. Often their consumption is subject to a voluntary restraint determined by social mores; you may want another slice of cake, another piece of chocolate, or another potato chip, but will often hold back to avoid seem-

ing intemperate. Because of the typically small portion sizes associated with moreish food, this may be an example of the appetizer effect, which occurs when the initial consumption of palatable foods increases appetite for further eating.

Explanations for craving, moreishness, and appetizer effects have recently focused on the brain’s biochemistry, in particular those functions mediated by opioid (morphinelike) peptides. Interfering with the functioning of this biochemical system using opioid blocking drugs leads to reduced food consumption overall and also to attenuation of appetizer effects, apparently because the foods become less palatable. Conversely, it is possible that increased opioid levels may induce cravings by making foods more palatable. Such changes may occur in a variety of circumstances—dieting, stress, exercise, alcohol consumption—all of which are known to influence the brain’s opioid systems.

Cravings thus tell us little about the body’s nutritional needs, beyond the fact that highly palatable foods tend to be high in energy. Other evidence also points to strategies to maximize energy intake. At least in Western countries, given ample availability, we tend to consume a diet that contains 35 to 40 percent fat, well in excess of what we need to survive. Moreover, from early infancy onwards, we will attempt to compensate for reductions in calories at one meal with an increase at the next.

In addition to energy intake, we seem predisposed, as omnivores, to seek variety in our diet. As noted in the section on sensory-specific satiety, this may be one way of optimizing survival through ensuring adequate nutrient intake. Classic studies on dietary self-selection were carried out by Clara Davis in the 1920s and 1930s. She allowed recently weaned infants access to a varied selection of foods and found that they first tasted widely and then developed preferences for a selection of these foods. This research has been often misinterpreted to suggest that the body has an innate wisdom, in that the foods the infants selected represented a balanced nutrient intake. This was inevitable, however, given the range of foods available.

This is not to say that mechanisms responsive to our needs are not in operation. On the contrary, the palatability of energy and sodium sources, the avoidance of toxins through dislike of bitterness, the rapid formation of aversions to foods associated with gastric illness, and the maintenance of nutrient variety via sensory-specific satiety, are all innate predispositions that modulate the hedonic value of sensory properties of foods to help ensure survival.

since pain avoidance is the simplest key to survival. How then to explain the fact that at least a quarter of the world's population each day consume (and presumably enjoy) a meal containing an extremely potent irritant, capsaicin, which is present in chilies? Whatever the source of our increasing preference for pungency in foods, it must be a potent mechanism. Apart from the warning signals for pain, our bodies possess a built-in response to high levels of irritation. This defensive reflex, as it is known, consists of increased blood flow to the head, profuse sweating, tearing, and nasal discharge—physiological changes that are thought to have evolved as a means of rapidly eliminating toxins. Although frequent consumers of spicy foods experience somewhat less intense physiological responses and burn than infrequent users, there is no doubt that the burning sensations are actually part of the reason these foods are consumed, not something to be tolerated for other reasons.

Both regular exposure, commencing during breastfeeding, and postingestional energy conditioning are likely to play a part in the development of liking for hot foods, particularly in countries whose staple diet includes high levels of spiciness. To explain the recent increase in liking for hot foods in Western countries, though, a number of other interesting mechanisms have also been proposed. These include the hypothesis that the painful experience may activate the brain's natural opioid (morphinelike) biochemical systems, dampening pain and producing a chili eater's "high." Alternatively, it has been suggested that we derive pleasure from the "thrill" of the benign but highly stimulating experience of consuming hot foods.

### **Where Do Differences in Food Likes Come From?**

If exposure, together with resultant learning processes, can substantially explain food preference development, what accounts for the differences in which foods we come to like? Exposure to flavors is now known to begin even prior to birth. Amniotic fluid, which comes into contact with the taste and odor receptors in the mouth and nose of the fetus, carries both taste and odor qualities. There is good evidence that the maternal diet during pregnancy can influence food preferences of the child following birth. Thus, it has been shown that infants whose mothers consumed carrot juice during pregnancy showed a greater liking for carrot-flavored cereal at six months of age than did a control group of children whose mothers consumed only water. Following birth, a wide range of flavors derived from the maternal diet is carried in breast milk, and this also influences an infant's later food preferences, including greater acceptance of novel flavors. In other words, the variety of a mother's diet can promote a varied set of food preferences in the infant. As a result, breast-fed babies are more likely to develop preferences following exposure to novel foods as infants. Whether this reflects early exposure to particular flavors, or a general effect of previous maternal dietary variety, is uncertain.

### **Social Influences**

From childhood on, social interactions, whether within the family or with other groups, provide the context within which the majority of food experiences occur, and hence by which learning of food likes is facilitated. The pleasure associated with such interactions—the conviviality of a meal shared with friends, for example—may represent just as positive a conditioning stimulus for a new food flavor as sweetness. Thus, it may be that our estimation of the food at a restaurant has as much to do with the social environment as it does with the chef's skills. In children, pairing foods with the presence of friends, a liked celebrity, or attention by adults all increase liking for those foods, no doubt reflecting the positive hedonic value of each of these groups to the child.

This process is strongly evident in the relative impact of different social interactions on the food preferences of children. Surprisingly, despite the enormous opportunities in a family for exposing children to the foods eaten by the parents, parental preferences are poor predictors of child food preferences; in fact, they are no better predictors than the preferences of other adults. This suggests that the extent to which these sets of preferences are related has more to do with the wider culture than with any specific food habits within the family. A child's food likes and dislikes are much more likely to be associated with those of peers, especially specific friends, than those of its parents. Peers may also be as effective as families at helping to overcome neophobia, since the food choices of both friends or well-known adults strongly influence a child's food choices. The ultimate impact of social facilitation of food choice is that the liking eventually becomes internalized. That is, foods chosen because others do so become liked for their own sensory properties.

### **The Cultural Context**

Dietary differences between cultures are almost always more pronounced than individual differences within a culture. The relatively limited amount of research that has been conducted on cross-cultural perceptions of sensory qualities finds fewer differences than are needed to explain the often markedly different preferences for foods. More plausibly, it is likely that differences in preferences reflect experiences with different foods. In addition to facilitating liking through exposure and the action of social influences, cultures act to define what substances are considered foods.

Foods that are unfamiliar to a culture may initially be seen as entirely unsuitable for consumption, while certain flavors may be regarded as inappropriate for specific foods. For example, bean paste is often used as a sweet filling in Japanese cakes, whereas in many Western countries, beans are expected to inhabit savory, not sweet, products. Again, porridge is either sweet or savory, depending on your heritage. In other cases, because of different histories of exposure, a preferred flavor in one

culture may be perceived as unpleasant in another. The odor and flavor of lamb and mutton are highly liked in the West but rejected in the many parts of Asia that do not have the history of consuming sheep meat. Foods may of course be the subject of religious or cultural taboos, or even not be defined as food at all. In Western countries, we are unlikely to ever develop a taste for dog meat or snake blood.

The notion of culturally specific flavor principles has been proposed as a way of categorizing cultural differences in cuisines. Flavor principles are unique combinations of specific ingredients used in a variety of foods within a culture. This combination provides a characteristic flavor that foods within the culture share, and identifies them as originating from that culture. For example, a characteristic combination of ingredients in Japanese cooking is soy sauce, mirin (sweet rice wine) and dashi (a stock made from flakes of the bonito fish, which is high in umami taste). While Korea is geographically close to Japan, its flavor principle could not be less similar, with the intense flavors of garlic, chili, sesame, and soy dominating many dishes. Flavor principles not only define the national cuisine, they also perform a social role by acting as an expression of the individuality of the culture.

Flavor principles may help to provide a solution to the “omnivore’s paradox” and the consequent neophobic response that novelty can elicit, thus limiting the foods available for consumption within a culture. A familiar flavor can provide a safe context for new foods, thus maximizing the breadth of the diet. On the individual level, recent findings suggest that a familiar sauce could increase the willingness of children to consume a novel food. A characteristic combination of flavorings may also provide variety and interest in diets dominated by bland staples such as corn or rice. Although a flavor principle might contain only a small set of characteristic seasonings, these can be combined in different ways. Moreover, what may appear to be a single ingredient or spice to an outsider may in fact have many subtle variations. Different chili varieties, for instance, vary considerably in the flavor and degree of heat that they impart to foods.

Increasingly, the food industry operates in a global setting. This is likely to mean that those foods that are purchased in your local supermarket are, or soon will be, also available on the other side of the world, perhaps within a culture whose cuisine is vastly different from your own. Whether this means that national flavor principles will ultimately be diluted or replaced is uncertain. Some evidence suggests they will not. Japanese urban populations have, for many years, enjoyed wide access to foods from other parts of the world, particularly Europe and the United States. Yet, while rice consumption has fallen and red meat and dairy food consumption has increased in recent years, there is little evidence that more traditional foods are disappearing. Moreover, Western food companies wishing to export to those cultures whose cuisines are substantially different are learning that in-

corporating aspects of the flavor principles of those cultures is essential for producing acceptable foods.

### **Food Choice: The Broader Context**

Although a food’s sensory properties may substantially determine what we like, they are only part of why we choose a particular food on a particular occasion. The determinants of our diet include factors that are both internal and external to the individual. Food choices are influenced by appetite, which in turn reflects when and what we last ate, and our overall state of physical and psychological health. In some extreme cases, these internal influences can render eating itself a pathological process, as in disorders such as anorexia and bulimia nervosa. Even in nonpathological circumstances, though, choosing a high-fat or -carbohydrate food may have more to do with our mood than anything else.

Liking is also heavily dependent on context. At its simplest level, cultural practices will determine whether or not we eat cooked meat or toast for breakfast. The extent to which either of these foods is acceptable will depend considerably on time of day. The same food can also vary in acceptability depending on where we experience it. Due to the influence of prior expectations, the same meal served in a restaurant is likely to be judged as more acceptable than if it is served in a student cafeteria.

Clearly, also, the reason why we first choose a food must be based on factors other than direct experience of, and therefore liking for, the sensory properties of the food. Food manufacturers and marketers rely on advertising and labeling to create a positive image for products, and attempt to create high (but not unrealistic) expectations for the product’s sensory properties. If the food meets those expectations following purchase, then the consumer is likely to try the product again. Repeat consumption and the consequent associative and post-ingestive processes will then act to promote increased liking for the product.

- ADDITIVES.** Food additives are regulated substances and therefore defined in law. Unfortunately, definitions vary among jurisdictions. A typical definition of a food additive may be: a substance the use of which in a food causes it to become a part of that food or to alter the characteristics of that food. A list of exceptions (Table 1) often follows because such a definition is vague and can include many substances not normally regarded as additives. Regulations are then required that control which additives can be added to which foods, and at what levels they can be added to those foods in which they are permitted.
- In the U.S. Code of Federal Regulations, Title 21—Food and Drugs (21CFR170.3), the following definition appears: “Food additives includes all substances not exempted by section 201(s) of the act, the intended use of which results or may reasonably be expected to result, directly or indirectly, either in their becoming a component of food or otherwise affecting the characteristics of food.”
- The European Union (1994) defined a food additive as “any substance not normally consumed as a food in itself and not normally used as a characteristic ingredient of food whether or not it has nutritive value, the intentional addition of which to food for a technological purpose in the manufacture, processing, preparation, treatment, packaging, transport or storage of such food results, or may be reasonably expected to result, in it or its by-products becoming directly or indirectly a component of such foods.”
- The Codex Alimentarius Commission (a joint Food and Agriculture Organization of the United Nations [FAO] and World Health Organization [WHO] organization established to develop uniformity of food standards for international trade) has defined a food additive as “any substance not normally consumed as a food by itself and not normally used as a typical ingredient of the food, whether or not it has nutritive value, the intentional addition of which to food for a technological (including organoleptic) purpose in the manufacture, processing, preparation, treatment, packing, packaging, transport or holding of such food results, or may be reasonably expected to result, (directly or indirectly) in it or its by-products becoming a component of or otherwise affecting the characteristics of such foods. The term does not include contaminants or substances added to food for maintaining or improving nutritional qualities” (Codex Alimentarius Commission, 1999).
- In the Canadian Regulations, Part B, Food, Division 1, General, B.01.001, p. 16, of the Canadian Food and Drugs Act (Amendments 1999), “food additive” is defined as “any substance the use of which results, or may reasonably be expected to result, in it or its by-products becoming a part of or affecting the characteristics of a food, but does not include (a) any nutritive material that is used, recognized, or commonly sold as an article or ingredient of food, (b) vitamins, mineral nutrients and amino acids,

John Prescott

### EXCEPTIONS OFTEN DECLARED BY GOVERNMENTS TO THE DEFINITION OF A "FOOD ADDITIVE"

#### *Exceptions to Definition of Food Additive*

- Flavoring preparations such as spices, natural extractives, oleoresins, essential oils, and seasonings
- Nutrients such as amino acids, vitamins, and mineral supplements, some of which may be regulated as to levels permitted in foods
- Any nutritive substance (that is, food ingredient) sold as an article of food or as an ingredient
- Certain permitted agricultural chemicals (used in growing plants) and drugs (administered to animals)
- Packaging materials and their components

other than those listed in the tables to Division 16, (c) spices, seasonings, flavouring preparations, essential oils, oleoresins and natural extractives, (d) agricultural chemicals, other than those listed in the tables to Division 16, (e) food packaging materials and components thereof, and (f) drugs recommended for administration to animals that may be consumed as food."

These definitions differ in their specificity, and exceptions to the definitions vary from country to country and trading bloc to trading bloc. These differences can be a source of confusion in the mind of the public regarding what food additives are, as well as a source of nontariff trade barriers between countries.

In the United States, there are two categories of exemptions to the definition (Food Additives Amendment 1958): prior-sanctioned items and GRAS (generally recognized as safe) items [21CFR170.3 (k, l, n, and o)]. The former category was sanctioned by existing legislation (prior to September 6, 1958) as outlined in the Federal Food, Drug, and Cosmetic Act, the Poultry Products Inspection Act, and the Meat Inspection Act. GRAS substances, so declared based on opinions of experts and an extensive history of use, are listed in forty-two categories and include salt, alcoholic beverages, cheeses, baked goods (mixes, flours, ready-to-bake products), condiments, fats and oils, and so forth. They can very loosely be described as the "ingredients" usually found in recipes. Also exempted are thirty-two categories of GRAS food chemicals, which can broadly be classed as processing aids.

In the Directive of the European Communities the exceptions to the definition are: processing aids (which

are further defined); agricultural chemicals used in conformity to European Community rules; flavorings as defined by Council Directive; and substances added to foods as nutrients.

### Indirect (Unintentional) and Direct Additives and "Carry-Over"

In addition to the definition of "additive" itself, there are also definitions of direct and indirect (unintentional) additives, and the principle of carry-over. Direct additives are added directly to foods for a specific aesthetic or technological purpose. They are usually declared on labels. Indirect additives become part of the food usually in trace amounts that are harmless to consumers and are present because of packaging, storage, processing, or handling. These are also referred to as unintentional additives. Their presence in foods results from the principle of "carry-over," that is, they are permitted agricultural chemicals used on farm products or accepted drugs and nutrients fed to animals. Such agricultural chemicals, even when used according to good husbandry practices, may end up in the food supply, or additives used as a component in ingredients may turn up in trace amounts in finished food products. Such substances are permitted only if the substance was permitted in the raw material or ingredient initially; the amount in the raw material does not exceed the maximum amount so permitted in the raw material or ingredient; and the amount carried over into the food does not exceed that expected by good manufacturing practice [see, for example, Codex Stan 192-1995 (Rev.2-1999) p. 3, Section 4].

### History of Food Additives

Substances have been added to foods to achieve some desirable characteristic in a finished food product for many hundreds, if not thousands, of years. For example, salt has been used to preserve hams as well as some hard sausages and salted cod; to flavor foods; and to control the fermentation of a variety of vegetables such as sauerkraut and *sauerrüben* (fermented rutabagas), and fish products (for example, *rollmops*, Bismarck herring, fish sauce, Malaysian *nuoc-mam*, shrimp paste, *belacan*, and anchovies). Historically bakers used fats to "shorten," that is, lubricate, dough for certain baking products. In these two examples, salt and certain fats have been used as processing aids.

Spices, herbs, and some vegetables were added to foods to develop unique and pleasing flavors, and in some cases to enhance or preserve foods. For example, Hartley, in *Food in England* (1985, p. 563), describes claims made by cider processors that straw mats (processing aids) used to separate layers of apples in presses for cider making produced the best cider because of the minerals drawn up by the straw from the soil. There are many kinds of leavening agents used in baking: yeast, sourdough starter cultures, baking soda and an acid (for example, soured milk) for soda breads, or commercially prepared baking

powder which contains the previous two agents (plus others) together in one mix. Salts of sulfurous acid (sulfites) are used to control the fermentation of grape musts and were also used by fraudulent butchers to give a fresher, brighter appearance to ground meats.

Prior to the development of food science and before the establishment of a rigorous system of food inspections, food manufacturers and food retailers often took advantage of this lack of good analytical methods for food products by mixing adulterants into foods to deceive the consumers. Elisa Maria Rundell in her book, *A New System of Domestic Cookery*, describes a procedure (1828, p. 336) to determine whether bread has been adulterated with whiting or chalk, commenting that this type of adulteration was common practice.

A. H. Hassall (1817–1894), an early food analyst, determined (ca.1850) that much of the coffee sold in England had, as “additives,” chicory, roasted wheat, burnt sugar for coloring matter, beans, and potato flour. An earlier chemist, Fredrick Accum (1769–1838), started one of the first training centers in practical (analytical) chemistry in England and reported such fraudulent practices as mustard adulterated with radish seed; vinegar sophisticated with sulfuric acid; cream enhanced with rice powder and arrowroot; cayenne pepper adulterated with red lead; and confectionery colored with vermilion (mercuric sulfide) (see also Skuse, c. 1900). The work of Accum, but primarily that of Hassall, led directly to the passing of food legislation preventing the adulteration of foods and drink in the U.K. (Farrer, 1996, 1997).

Traditionally, innocent additives have been added to foods. Cooking skills passed on from mothers to daughters and often to be found in some of today’s older cookbooks taught the use of unripe apples (or apple skins) to assist the gelling of fruit jams; lemon juice added for acidification of foods; and Hart’s horn (deer antler) shavings used for gelation. Today, the active components of these natural ingredients, pectin in the apples, citric acid in the lemons, and gelatin in the antlers are well-recognized food additives.

In many people’s minds, however, food additives are considered to be a suspicious, comparatively modern invention created in large part by food manufacturers to cheapen products and hoodwink the public.

In earlier times, there was some truth to this suspicion. Today, this is far from the truth. There was, and is, an absolute need for improved processing aids to satisfy the demands by consumers for attractive, tasty, safe food products of uniformly high quality as well as for new products.

In the United States, individual states were the first to develop food legislation and a system of food inspection. In terms of federal legislation, the Federal Food and Drugs Act of 1906, popularly known as the Pure Food Law, for prevention of adulteration of foodstuffs, was

In Skuse’s *Complete Confectioner* (10th ed.), published ca. 1900, the author found it necessary to list poisonous colors that confectioners should avoid. Among those he listed are chrome yellow (lead chromate), sulfate of arsenic, red lead, and copper sulfate. Skuse noted that he “knows sugar boilers who are very partial to use a little chrome yellow for stripes.”

\* \* \*

Marketing people and retailers often defend adding color and flavor to processed foods. Only safe, attractive, nutritious, and flavorful food can be marketed successfully and therefore only such foods will be purchased by consumers. It is only these foods that are ultimately consumed. Good nutrition can be maintained within the population only if attractive, wholesome foods are presented.

\* \* \*

Chicory, considered an adulterant in ground coffee, is also used as a coffee-substitute beverage in its own right and is often added to some coffees to give a richer, stronger, roasted flavor to the final beverage.

passed, and came into force on January 1, 1907. It dealt largely with adulteration and misbranding of foods.

### The Need for Additives

Using such natural products as apple skins or lemon juice as food processing aids causes problems in large-scale manufacturing situations. First, the desired active ingredients in natural products are not consistent in quality, properties, versatility, or concentration in their natural state. Furthermore, they may bring both undesirable flavor attributes, associated with their source, to the finished product, as well as microbiological contamination. For example, using orange or lemon juice to acidify a food inevitably brings the flavor of oranges or lemons, which may not be desired in the finished product. It would be the rare householder who would want to make her own red color by crushing the dried insect used to make an extract of cochineal for baking or candy making.

Consumers who shop for groceries only once a week or even only once every two weeks still want their food purchases to remain as fresh, wholesome, and safe as the day they were purchased. The consumer’s demand for manufactured, prepared foods that have a high uniform quality with good shelf life characteristics and are as close to the natural state as possible has been the major determinant for an increase in the use of additives. Additives preserve color and flavor as well as maintaining safety and nutritive value throughout both processing and the product’s shelf life.

## NEED FOR FOOD ADDITIVES IN MANUFACTURING

### *Quality Characteristics in Processed Foods Demanded by Consumers that Require Use of Additives in Manufacturing*

- Uniformity of products sold by count, size, shape, volume, or weight
- Desire for fresh, semiprepared foods “as fresh and natural appearing as possible” with a safe, long shelf life
- Replacement of nutrients lost or reduced in processing as well as the addition of other health-giving properties equivalent to the unprocessed product
- Additions of special nutrients or other substances for foods for consumers with special nutritional needs
- Dietetic foods with same eating characteristics (flavor, taste, color, texture, and mouth feel) as the regular product
- Flavor, color, and texture (crispness, eye appeal, or moistness) of unprocessed, natural product
- Unique characteristics such as spreadability at room temperature, adherence, flow properties
- Enhancement of keeping qualities and organoleptic characteristics of processed foods for eating enjoyment

The box above lists some quality characteristics consumers prefer that require food additives to be added to foods. For example, in dietetic foods (low-salt, low-fat, low-sugar, or lactose-free foods), there must be some alternative substance (an additive) to replace the taste impact that salt provides, or to provide the mouth feel found in full-fat foods, to replace the sweetness provided by sugar, or to remove (along with the enzyme lactase) the lactose inherent in milk products. Hence there was a need for new additives that were either synthesized *de novo*, extracted and purified from natural sources (these additives are termed “nature identical”), or modified chemically to provide unique properties not found with nature-identical substances, for example, modified starches. Some of these properties are resistance to heat and acetic acid, constant viscosity in sauces during prolonged heating or without prolonged storage, special textures such as creaminess or pulpy granularity, or pregelatinization for “instant” rices. Thus, along with consumers’ desire for a decreased use of additives there is also a need for newer and more effective additives (Smith, 1993).

## Classification and Functions of Additives

Additives perform a specific and necessary aesthetic or functional role in foods. If they did not have a purpose, no government would have considered allowing them. Many additives have several different functions depending on the foods they are added to. In addition to their flavoring and nutritive properties, some herbs, spices, vegetables, and vitamins added to foods have other functional properties as processing aids. For example, vitamin C (ascorbic acid) and vitamin E (tocopherols) are both excellent antioxidants and are used to remove oxygen and prevent oxidation, thus extending the shelf life of many food products. Garlic has long been used for its antimicrobial properties. Thyme and oregano contain thymol, which has a wide spectrum of antimicrobial effectiveness (Beuchat and Golden, 1989).

The only practical way to classify additives is by the purpose for which they are added to foods. The table presents one classification of additives with some typical examples within each classification and examples of foods in which they may be found.

**Colors.** Colors are either water soluble or oil soluble (see Carriers, extractants, and solvents) and are designed for specific application in aqueous or oily foods. There are three categories of colors: natural or nature-identical, synthetic, and inorganic. Natural or nature-identical colors (colors extracted from natural products or synthesized to resemble their natural counterpart) have two disadvantages. They are frequently mixtures and are, in general, not as stable in foods as are the synthetic colorants. Many change color with the acidity or alkalinity of the food they are added to; many are susceptible to breakdown by oxidation and heat. Synthetic colors are preferred colorants in foods, but questions of their safety have arisen in the past and hence there is widely differing acceptance of their use in many foods by different countries. Inorganic colorants are very stable but have a limited use in foods such as sugars, jams, and confectionery.

In most instances, colorants are permitted according to “good manufacturing practices,” that is, governments, working closely with food manufacturers and with the advice of experts, have established minimal, acceptable levels of usage in practice.

**Enzymes.** Enzymes are biological catalysts that can break down specific materials (substrates) into simpler components or cause changes in the substrate’s structure. Carbohydrases break down complex sugars (for example, starches, cellulose, lactose, maltose, and so on) into simpler sugars (saccharification). Lipases break down fats into glycerol and fatty acids. Proteases break down proteins into their constituent amino acids. Other enzymes act as preservatives and scavenge oxygen that may be dissolved in plant tissues or in headspaces in packages and remove it.

TABLE 1

**Classification of additives according to functions with examples and products they might be used in<sup>a</sup>**

Function or category of additive	Typical examples of additive <sup>b</sup>	Products benefited by addition <sup>c</sup>
Coloring agents		
Natural or nature-identical	Annatto, carotenes, chlorophyll, cochineal, paprika, turmeric, anthocyanins	Fruit jams, jellies, and marmalades; ice cream and ice cream mixes, cheeses; pickles and relishes; butter; liqueurs and cordials
Synthetic	Tartrazine, amaranth, allura red, sunset yellow	Similar to above
Inorganic	Titanium dioxide, iron oxide, silver metal, aluminum metal	Certain sugar products, jams; surface colorants of confectionery products
Enzymes		
Carbohydrases	Amylase, cellulase, invertase, lactase, pullulanase, pentosanase, glucose isomerase	Ale, beer, malt liquor, cider wine, bread, flour; mash, coffee and tea extracts, fruit juice; liquid and soft-centered confectionery; reduced-lactose products; bread, flour, production of dextrins, maltose; ale, beer, bread, fructose syrups
Lipases	Lipase	Dairy-based flavorings, cheeses, modified fats for dietetic foods, bread, flour
Proteinase	Bromelain, ficin, papain, pancreatin, pepsin, protease, rennin	Beer, malt liquor, bread, flour, cheeses, meat-tenderizing preparations, precooked cereals, milk, animal and vegetable hydrolysates, meat pickles
Preservation	Catalase, glucose oxidase	Oxygen scavengers used in egg products and dairy products
Carriers or extractants	Acetone, benzyl alcohol, carbon dioxide, ethyl acetate, tributyrin, mono- and diglycerides, hexane	Spice extracts; flavoring preparations; added to coffee and tea for decaffeination; hops extraction, fats and oils seed meals
Sweeteners	Aspartame, mannitol, sorbitol, xylitol, isomalt, sucralose, thaumatin	Dietetic foods (low calorie), soft drinks, bakery products, confectionery
Preservatives	Acetic acid, ascorbic acid and salts, sodium and potassium nitrates, sodium and potassium nitrites, wood smoke, benzoic acid and salts, sulfurous acid and salts, propionic acid and salts, sorbic acid and salts, ascorbyl palmitate and stearate, BHA, BHT, citric acid and salts, propyl gallate, tartaric acid	Meat and meat products, cured meat and fish products, fish and fish products, ale, beer, cider, malt liquor, cheeses and cheese spreads, canned or frozen fruit and vegetable products, fruit beverages, seafood products, bread and baked goods, fats, oils, and so forth
Bleaching, maturing, and dough conditioning agents	Ammonium persulfate, ascorbic acid, benzoyl peroxide, chlorine and chlorine dioxide, sodium sulfite, potassium iodate	Flour, whole wheat flour, bread, cake mixes, some dough mixes
Anticaking agents	Silicon dioxide, magnesium stearate, cellulose, various calcium salts	Salt, baking powder, and other dry mixes and powders
Emulsifying, gelling, stabilizing, and thickening agents	Various plant and microbial gums and polysaccharides and salts thereof, gelatin, pectin, acetylated monoglycerides, lecithin, methyl cellulose, various calcium and magnesium salts	Used in a wide range of food products from alcoholic beverages to milk and dairy products, fruit and vegetable products, to meat and meat products and oils and margarines
Firming agents	Aluminum, calcium, and sodium salts of various acids, for example, aluminum sulfate of calcium lactate	Canned fish and fish products, canned fruit and vegetable products, pickles and relishes
Glazing and polishing agents	Various gums and waxes, for example, beeswax, gum arabic, mineral oil, acetylated monoglycerides	Primarily confectionery products
Buffering agents, pH adjusting agents, acid reacting materials, and water correcting agents	Acetic acid and various salts, ammonium aluminum sulfate, ammonium or calcium hydroxide, citric acid and various salts, salts of phosphoric acid, cream of tartar	Baking powder, cocoa products, cheeses, ice cream mixes, alcoholic beverages, fruit and vegetable products
Sequestering agents	EDTA and salts thereof, citric acid and its salts, phosphoric acid and its salts	Pumping pickles, alcoholic beverages, canned seafood (lobster, clams, sea snails, and so forth), dairy products, meat and poultry products
Starch modifying agents	Hydrogen peroxide, nitric acid, peracetic acid, sodium hydroxide, sulfuric acid	Starch
Yeast foods	Ammonium, calcium, potassium and zinc salts of various acids such as phosphoric, carbonic, and citric	Flour, bread, some alcoholic beverages, bacterial starter cultures

*Abbreviations:* BHA, butylated hydroxyanisole; BHT, butylated hydroxytoluene; EDTA, ethylenediaminetetraacetic acid.

<sup>a</sup>In reading this table, it is important to recognize that regulations regarding food additives (1) vary from country to country, (2) vary both with the levels of use permitted in foods and with the foods to which they may be added, and (3) are constantly being reviewed regarding their need and safety as new research emerges and newer and better additives are developed (Smith, 1993). Information provided here should not be interpreted as indicating that any food application is permissible in any specific country.

<sup>b</sup>The listing of examples of additives is not complete.

<sup>c</sup>The listing of examples of products is not complete.

Electron micrograph of a crystal of monosodium glutamate. MSG is one of the most widely used additives in food, and some people suffer reactions to it, especially a swollen liver, which extends the stomach and creates the discomforting sensation of having overeaten. COURTESY OF PHOTO RESEARCHERS, INC.

Many enzymes are derived from natural sources, for example, rennet from stomachs of calves, sheep, and goats; bromelain and papain from pineapples and papaya, respectively; ficin from latex of fig trees; pancreatin from the pancreas of pigs and oxen. However, an ever-growing number of enzymes are derived from microorganisms such as *Bacillus subtilis*, various species of molds especially *Aspergillus* varieties, and yeasts.

**Carriers, extractants, and solvents.** Carriers and extractants are used to extract flavoring compounds from spices and herbs to produce oleoresins; soluble solids from tea leaves; and coffee beans for the preparation of soluble drinks and for the selective extraction of caffeine in decaffeinated coffees; preparing hop extracts for beers; and extraction of cocoa powder. They are also used to extract fats and oils from oil seeds (defatting) and to dissolve oil-soluble dyes and flavorings, thereby serving as carriers to be added to other foods.

**Sweeteners.** There are two types of sweeteners: caloric sweeteners that provide minimal calories (usually only 1 or 2 calories) based on their sweetening power compared

to that of sucrose, the sweetener they are replacing, and noncaloric sweeteners, which provide no calories. In U.S. regulations, caloric sweeteners as defined here are referred to as “non-nutritive sweeteners” and further defined as “substances having less than 2 percent of the caloric value of sucrose per equivalent unit of sweetening capacity.”

**Preservatives.** A wide variety of additives are used for preventing or delaying spoilage and are closely restricted in respect to the foods they can be used with and the levels at which they can be used. Some preservatives, such as acetic acid, wood smoke, ascorbic and erythorbic acids, lecithin (component of egg yolk and soybeans), citric acid, and tartaric acid, are generally permitted according to good manufacturing practice. However, sulfurous acid and its salts (sulfites) can cause serious problems in some asthmatics and regulations permit only low levels to be used. Nitrite and nitrate salts, used in meat curing, have been determined to be potential sources of cancer-causing agents and only minimal levels are permitted to be used.

**Bleaching, maturing, and dough conditioning agents.** These agents are used for whitening flour and improving (maturing and conditioning) flour’s baking characteristics in the many varieties of bakery products.

**Anticaking agents.** These agents reduce the tendency of granulated products (dry mixes, dried egg powders, salt, and so forth) to stick together and help them keep their free-flowing properties.

**Emulsifying, gelling, stabilizing, and thickening agents.** Emulsifying agents are used in the formation of stable oil-and-water or oil-and-vinegar mixtures. Gelling, stabilizing, and thickening agents form soft gelled structures, thicken suspensions of particulate foods and prevent their separating, and provide mouth feel as bulking agents in low-calorie foods. They are also used to prevent or slow crystallization (staling) in foods.

**Firming agents.** These agents prevent or inhibit the softening of processed fruits and vegetables, especially during the process of canning in which they receive a severe heat treatment.

**Glazing and polishing agents.** These agents put a protective surface or coating or polish on a food, particularly confectionery products but also some vegetables and fruits.

**pH-Adjusting, acid-reacting, and water-correcting agents.** These agents maintain the acid-alkali balance (that is, pH) of foods at a desired level. Many delicate products such as artichokes must be acidified in order to be thermally processed (canned) with a less severe heat process because the usual high temperatures used for canning vegetables would destroy their shape and texture. Acids are also required to release carbon dioxide from leavening agents.

**Sequestering agents.** These agents act as sponges to gather or reduce in concentration any trace metal ions (especially copper and iron) that might, for example, pro-

mote oxidation or otherwise cause spoilage in foods. They improve the quality, color, and stability of canned products.

**Starch-modifying agents.** These agents can be used only to modify the properties of starch for its use in mixes, sauces, and custards.

**Yeast foods.** As their name suggests, these agents are used in fermentations with yeast and serve as a food for the yeast in the preparation of the inoculum. An inoculum is a highly concentrated suspension of yeast (or other microorganisms) to be added to malt mash for beer-making or to bread doughs for leavening purposes or wherever fermentation is desired.

**Miscellaneous additives.** Propellant gases for the dispensing of foams or aerosol foods are also additives.

### Regulation, Control, and Safety of Food Additives

Countries with well-developed food manufacturing industries have food legislation and associated regulations governing the use of food additives. In trade, where regulations between countries may differ, countries may allow conditional entry (where safety is not a concern) requiring relabeling of an offending product or specify compliance to Codex Alimentarius Commission standards before permitting importation.

The process for revoking approval or modifying the conditions of approval of existing food additives or for approving new ones varies from country to country. As problems of public health significance emerge that are attributable to the use of an additive, that information is assessed by panels of experts in the fields of epidemiology and toxicology. Should questions of safety emerge regarding the use of any prior approved additive, an evaluation must be made of the risk/benefit problems associated with continued use (Institute of Food Technologists, 1978). An excellent example of such a risk/benefit assessment can be found in the continued use of nitrate/nitrite salts in cured meat products. Banning the use of the salts in cured meats would most certainly expose the consuming public to the greater danger of botulism poisoning. The absence of these salts would permit the growth of *Cl. botulinum* in the cured meat and certainly the associated development of the *botulinum* toxin. On the other hand, these salts are also able under some circumstances to form nitroso-compounds, which are very active carcinogens.

However, there are general principles to guide the use of food additives and the assessment of new ones. No food additive is permitted for use until its safety has been assessed by expert panels of specialists. It is up to the petitioner for use of an additive to supply toxicological data to the government-appointed panel. Evaluations, based on a generally accepted protocol, must be made of the toxicological effect of the additive (Winter and Francis, 1997). Animal testing is required to determine levels of toxicity which are then used to determine human toxicity

## GENERAL PRINCIPLES GUIDING THE USE OF FOOD ADDITIVES

### *Requirement for Uses of Additive*

- The additive must serve a useful purpose in preparing, processing, storage, and handling of the food
- The use of the food additive should not deceive, mislead, or defraud the consumer
- The use of the additive should not pose a health hazard either to the general population or to any special segment within the population

levels, but if the additive is substantially the same as the natural prior sanctioned or GRAS product, animal testing may not be required.

Toxicity data that are submitted for evaluation are based on assessment of exposure; such data must also determine the level of exposure. This will be influenced by the level used in foods (which is kept to the minimum level to produce the desired effect) and the level that remains in the food after processing. Other factors affecting the dose level are the age and gender of the consumer eating the food; the physical state of that individual (that is, pregnant, lactating, convalescent, with reduced immune system, with allergies, with special diet requirements, and so on); frequency of eating the food to which the additive is added; and the composition of the rest of the diet, which can have a protective effect on the toxicity.

Prior sanctioned additives are regularly reviewed for safety. Submissions for the approval of new additives may take several years and cost many hundreds of thousands of dollars to the petitioner. Such submissions are not undertaken lightly. The consumer's demand for innovative foods with new properties and enhanced safety will certainly see the food industry develop more and functionally better additives that are safe.

**ADULTERATION OF FOOD.** "Adulteration" is a legal term meaning that a food product fails to meet federal or state standards. Adulteration usually refers to noncompliance with health or safety standards as determined, in the United States, by the Food and Drug Administration (FDA) and the U.S. Department of Agriculture (USDA).

### Definition of Adulterated Food

The Federal Food, Drug, and Cosmetic (FD&C) Act (1938) provides that food is "adulterated" if it meets any

one of the following criteria: (1) it bears or contains any "poisonous or deleterious substance" which may render it injurious to health; (2) it bears or contains any *added* poisonous or *added* deleterious substance (other than a pesticide residue, food additive, color additive, or new animal drug, which are covered by separate provisions) that is unsafe; (3) its container is composed, in whole or in part, of any poisonous or deleterious substance which may render the contents injurious to health; or (4) it bears or contains a pesticide chemical residue that is unsafe. (Note: The Environmental Protection Agency [EPA] establishes tolerances for pesticide residues in foods, which are enforced by the FDA.)

Food also meets the definition of adulteration if: (5) it is, or it bears or contains, an unsafe food additive; (6) it is, or it bears or contains, an unsafe new animal drug; (7) it is, or it bears or contains, an unsafe color additive; (8) it consists, in whole or in part, of "any filthy, putrid, or decomposed substance" or is otherwise unfit for food; or (9) it has been prepared, packed, or held under unsanitary conditions (insect, rodent, or bird infestation) whereby it may have become contaminated with filth or rendered injurious to health.

Further, food is considered adulterated if: (10) it has been irradiated and the irradiation processing was not done in conformity with a regulation permitting irradiation of the food in question (Note: FDA has approved irradiation of a number of foods, including refrigerated or frozen uncooked meat, fresh or frozen uncooked poultry, and seeds for sprouting [21 C.F.R. Part 179].); (11) it contains a dietary ingredient that presents a significant or unreasonable risk of illness or injury under the conditions of use recommended in labeling (for example, foods or dietary supplements containing aristolochic acids, which have been linked to kidney failure, have been banned.); (12) a valuable constituent has been omitted in whole or in part or replaced with another substance; damage or inferiority has been concealed in any manner; or a substance has been added to increase the product's bulk or weight, reduce its quality or strength, or make it appear of greater value than it is (this is "economic adulteration"); or (13) it is offered for import into the United States and is a food that has previously been refused admission, unless the person reoffering the food establishes that it is in compliance with U.S. law [21 U.S.C. § 342].

The Federal Meat Inspection Act and the Poultry Products Inspection Act contain similar provisions for meat and poultry products. [21 U.S.C. §§ 453(g), 601(m).

### Poisonous or Deleterious Substances

Generally, if a food contains a poisonous or deleterious substance that may render it injurious to health, it is adulterated. For example, apple cider contaminated with *E. coli* O157:H7 and Brie cheese contaminated with *Listeria monocytogenes* are adulterated. There are two exceptions to this general rule. First, if the poisonous substance is inherent or naturally occurring and its quantity in the

food does not ordinarily render it injurious to health, the food will not be considered adulterated. Thus, a food that contains a natural toxin at very low levels that would not ordinarily be harmful (for instance, small amounts of amygdalin in apricot kernels) is not adulterated.

Second, if the poisonous or deleterious substance is unavoidable and is within an established tolerance, regulatory limit, or action level, the food will not be deemed to be adulterated. Tolerances and regulatory limits are thresholds above which a food will be considered adulterated. They are binding on FDA, the food industry, and the courts. Action levels are limits at or above which FDA *may* regard food as adulterated. They are not binding on FDA. FDA has established numerous action levels (for example, one part per million methyl mercury in fish), which are set forth in its booklet *Action Levels for Poisonous or Deleterious Substances in Human Food and Animal Feed*.

If a food contains a poisonous substance in excess of a tolerance, regulatory limit, or action level, mixing it with “clean” food to reduce the level of contamination is not allowed. The deliberate mixing of adulterated food with good food renders the finished product adulterated (FDA, *Compliance Policy Guide* [CPG § 555.200]).

### Filth and Foreign Matter

Filth and extraneous material include any objectionable substances in foods, such as foreign matter (for example, glass, metal, plastic, wood, stones, sand, cigarette butts), undesirable parts of the raw plant material (such as stems, pits in pitted olives, pieces of shell in canned oysters), and filth (namely, mold, rot, insect and rodent parts, excreta, decomposition). Under a strict reading of the FD&C Act, any amount of filth in a food would render it adulterated. FDA regulations, however, authorize the agency to issue Defect Action Levels (DALs) for natural, unavoidable defects that at low levels do not pose a human health hazard [21 C.F.R. § 110.110]. These DALs are advisory only; they do not have the force of law and do not bind FDA. DALs are set forth in FDA’s Compliance Policy Guides and are compiled in the *FDA and Center for Food Safety and Applied Nutrition (CFSAN) Defect Action Level Handbook*.

In most cases, DALs are food-specific and defect-specific. For example, the DAL for insect fragments in peanut butter is an average of thirty or more insect fragments per 100 grams (g) [CPG § 570.300]. In the case of hard or sharp foreign objects, the DAL, which is based on the size of the object and the likelihood it will pose a risk of choking or injury, applies to all foods (see CPG § 555.425).

### Economic Adulteration

A food is adulterated if it omits a valuable constituent or substitutes another substance, in whole or in part, for a valuable constituent (for instance, olive oil diluted with tea tree oil); conceals damage or inferiority in any man-

ner (such as fresh fruit with food coloring on its surface to conceal defects); or any substance has been added to it or packed with it to increase its bulk or weight, reduce its quality or strength, or make it appear bigger or of greater value than it is (for example, scallops to which water has been added to make them heavier).

### Microbiological Contamination and Adulteration

The fact that a food is contaminated with pathogens (harmful microorganisms such as bacteria, viruses, or protozoa) may, or may not, render it adulterated. Generally, for ready-to-eat foods, the presence of pathogens will render the food adulterated. For example, the presence of *Salmonella* on fresh fruits or vegetables or in ready-to-eat meat or poultry products (such as luncheon meats) will render those products adulterated.

For meat and poultry products, which are regulated by USDA, the rules are more complicated. Ready-to-eat meat and poultry products contaminated with pathogens, such as *Salmonella* or *Listeria monocytogenes*, are adulterated. (Note that hotdogs are considered ready-to-eat products.) For raw meat or poultry products, the presence of pathogens will not always render a product adulterated (because raw meat and poultry products are intended to be cooked, and proper cooking should kill pathogens). Raw poultry contaminated with *Salmonella* is not adulterated. However, USDA’s Food Safety and Inspection Service (FSIS) has ruled that raw meat or poultry products contaminated with *E. coli* O157:H7 are adulterated. This is because normal cooking methods may not reduce *E. coli* O157:H7 below infectious levels. *E. coli* O157:H7 is the only pathogen that is considered an adulterant when present in raw meat or poultry products.

### Enforcement Actions against Adulterated Food

If a food is adulterated, FDA and FSIS have a broad array of enforcement tools. These include *seizing* and *condemning* the product, *detaining* imported product, *enjoining* persons from manufacturing or distributing the product, or *requesting a recall* of the product. Enforcement action is usually preceded by a Warning Letter from FDA to the manufacturer or distributor of the adulterated product. In the case of an adulterated meat or poultry product, FSIS has certain additional powers. FSIS may *suspend* or *withdraw* federal inspection of an official establishment. Without federal inspection, an establishment may not produce or process meat or poultry products, and therefore must cease operations. With the exception of infant formula, neither FDA nor FSIS has the authority to require a company to recall an adulterated food product. However, the ability to generate negative publicity gives them considerable powers of persuasion.

State regulators generally have similar enforcement tools at their disposal to prevent the manufacture and distribution of adulterated food. In addition, many states have the authority to immediately embargo adulterated

food and to impose civil fines. Federal agencies often will coordinate with state or local authorities to remove unsafe food from the market as quickly as possible.

**ADVERTISING OF FOOD.** The word “advertising” is derived from the French *avertissement*, a giving notice or announcement. An advertisement is information that is publicly communicated through mass communication. The business of advertising is an aspect of commerce that is an integrated part of industrialized and affluent societies that can afford to purchase goods. Advertising brings notice to a wide range of consumer products, including food, a major consumer of advertising. In the United States in the 1990s, food and beverages together formed the most heavily advertised type of product: approximately 40 to 50 percent of television commercials are for food products, amounting to between ten and fifteen commercials every hour. Advertising takes place at a number of levels in the food marketing chain. Advertisements—ads in the United States and advertises in Britain—may be issued by manufacturers individually or as a group, by a marketing board representing a generic product, and by wholesalers, retailers, and distributors.

Although advertising has a long history, modern advertising began with the invention of printing in the six-

teenth century. Early advertisements for foods, which were presented alongside those for books, medicines, cures, and remedies, tended to be for foods and drinks that were at first consumed by the upper classes. English weeklies first reported coffee in 1652, chocolate in 1657, and tea in 1658. The widespread expansion of print advertising did not take place until the eighteenth and nineteenth centuries. Its spread was stimulated and encouraged by changing and developing trade patterns, especially the rail network and the improvement of roads. Improved means of transportation allowed for the expansion of extended regional and national trade networks. As the production of goods increased, they had to be more efficiently and effectively distributed and marketed. As much of the early advertising was contained in print media, the spread of literacy, together with the steep rise in the development of newspapers and magazines, especially after 1850, stimulated its development. It is in the last hundred years that advertising has developed into a major industry. So important has it become that it is central to the production of general communications and provides the economic basis that enables them to exist. It is also central to the development and existence of many products.

#### Functions of Advertising

Advertising has a number of functions. It is used to launch new food products. The advertising campaign for Nescafé instant coffee granules in the 1950s allowed it to gain a foothold in a market that had strong competition from other brands such as Maxwell House, “America’s favorite coffee.” It is used to extend the sale of products that are already established in the marketplace. In 1956 the advertising campaign for the biscuit Snack, manufactured by Cadbury, caused an immediate increase in sales. Although its initial impact was not maintained, sales remained higher than the earlier unadvertised level for a year or so, even when there was almost no advertising support given to it. Advertising is used to promote the growth of a product. A marketing campaign for Callard & Bowser Butterscotch in 1959 and 1960 caused its consumption to expand by around 20 percent. Advertising also created a continued demand for a product when the original need to consume it had become redundant due to changing social and economic conditions. Bovril, fluid beef, was developed in the 1870s as a convalescence food and was later used as an energy food on expeditions and during sporting events. With higher incomes, better eating, changing drinking habits (for example, the increased consumption of coffee over tea, and the popularity of carbonated, or “fizzy,” drinks), and the availability of new drinks, the original rationale for the consumption of Bovril had declined by the post–World War II years. An advertising campaign was introduced to remove the idea that it was an old-fashioned drink and to suggest that it was a “contemporary” one. Advertising has been used to slow down the decline in the consumption of a product. When milk consumption was falling in the postwar pe-

riod in Britain, especially in the mid-1950s, the National Milk Publicity Campaign succeeded in slowing down the rate of decline and in introducing new outlets that served to stimulate consumption.

### Costs of Advertising

Large sums of money are spent on food advertising. In Great Britain in 1999 the top food advertiser was Mars, a confectionery firm, which spent \$99,488,921 (£63,629,000) on its advertising; the second, spending \$82,966,590 (£53,062,000), was Kellogg's (GB), followed by the supermarket chain J. Sainsbury with \$76,846,990 (£49,151,000). The top brand was McDonald's fast-food restaurants, which spent \$66,260,524 (£42,379,000). Other highly advertised brands include the other fast-food restaurants, Kentucky Fried Chicken \$19,279,797 (£12,331,000) and Burger King \$17,604,550 (£11,259,000). Among the high food advertisers were supermarkets that promoted both their stores and their branded products. Sainsbury's was the top supermarket brand (\$45,528,848, or £29,118,000) followed by Tesco (\$28,564,912, or £18,286,000), then Asda (\$25,034,171, or £16,010,000).

As these figures suggest, not all foodstuffs are advertised to the same extent. In Britain in 1999, highly advertised foods include cereal products, confectionery, ice cream, potato crisps, snacks and nuts, margarine, low-fat spreads, and cheese. By comparison, small sums are spent on herbs and spices, excluding pepper and curry. Advertising-to-sales ratios vary greatly between products. For herbs and spices and fresh vegetables the figure may be as low as 0.06 percent and 0.07 percent respectively. Many foods had less than a 1 percent ratio. Intensive advertising at 11.31 percent was noted for cereals. Generally, advertising of food products shows a lower percentage of expenditure than that of other products, including alcoholic drinks and tobacco.

### Advertising Media

Food is advertised through a number of channels. As new technologies have become available, the opportunities for advertising have broadened. A number of these are especially important. Newspapers and magazines have long been a significant vehicle for advertising. Newspapers in Britain published advertisements in the seventeenth century, and, as the provincial press expanded, greater opportunities became available for food advertising. In the later nineteenth century, magazines increasingly started to carry advertisements: In the United States in the 1930s, some 20 percent of products advertised in the major print advertising media of women's and domestic magazines were for food and drink products. When radio networks were established (in 1926 and 1927 in the United States), they used advertising to bring in revenue. Food and drink manufacturers sponsored programs and also advertised their products in short "commercial breaks." In the 1950s television introduced a further medium that owes its ef-

fectiveness to the wide range of means that can be used to promote a product: moving pictures, sound (voice and music), and the written word. In the late twentieth century the introduction and extended use of the World Wide Web and e-commerce had an enormous initial growth. In the United Kingdom, growth rates for online marketing since the mid-1990s have been consistently well in excess of 100 percent, year after year. Internet advertising is undertaken through a number of means. In the year 2000, the majority (81 percent) of advertising took place through banners, and small numbers through sponsorship (9 percent), classified advertisements (7 percent), and other means (3 percent). Internet advertising includes sites from manufacturers, product manufacturing boards, supermarkets (which allow for online shopping and home delivery), and food enthusiast sites (for example, for British products in the United States).

Other media have provided further means of advertising food. Billboards and hoardings were first used for this purpose in Britain in the 1890s and are found over a wide geographical area. Light displays in cities, such as those for the carbonated drink Irn-Bru in Glasgow and Coca-Cola in London, have presented advertisements as visual images within central cityscapes. Buses and electric cars (especially since the 1890s in the United States) have carried advertising, usually on their sides or rear. Manufacturers advertise their products on their distribution vans; some also have special promotional vehicles that they use in campaigns where they take their product to public places or special shows to advertise it. Sponsorship of major public popular and sporting events is undertaken by a number of manufacturers. Flora margarine, made from sunflower oil, which is high in essential polyunsaturates, has been the sponsor of the London marathon in the late 1990s; the Bell's open golf championship is sponsored by Bell's, the whiskey manufacturer.

Advertising and promotion of foods is undertaken within the retail industry. Fancy displays draw attention to one or a range of products. In Britain, displays from the 1860s included decorative tins with hinged lids developed by the biscuit manufacturer Huntley and Palmers of Reading. As self-service supermarkets developed, largely after World War II, products could be displayed to draw special attention to them. Three-dimensional displays promoted a single product or a range, and tended to be developed by manufacturers. Supermarkets sometimes hold special testing events where customers can sample a product, thereby encouraging them to buy it. Food is also sold in special promotional packets, sometimes at a "special introductory price" or a "special promotional price." These may hold a sample of the product that can be packaged in a way that reflects the packaging on the regular-sized product.

A range of ephemeral material is distributed to food wholesalers and retailers by manufacturers and others involved in processing and distribution. Some of this, including calendars, pens, and pads of headed note paper,

is intended to remind the consumer of the product on a daily basis.

Coupons, which allow the consumer to receive a discount on the product when they present one to a retailer, are found in a range of print media, especially newspapers and magazines.

The medium that is used to advertise a product is selected for its appropriateness to that product, the nature and scope of the advertising campaign, and its desired target audience. Each medium has its own values and qualities. When television started to become widely adopted in Britain in the mid-1950s, Bird's Eye decided to use this new medium to advertise its frozen food products. The company was aware that families with televisions were more likely to be interested in new ideas such as Bird's Eye's products. At that time it was recognized that there was a potentially large market for frozen food, which was a relatively new phenomenon. In the 1920s daily newspapers were best suited to advertise foods and other products that were bought on a regular basis. Magazines that were to be read by a particular social class or group carried advertisements for foods and other products that would likely be consumed by them.

### Advertising Targets

Much food advertising is targeted at women, the main buyers of food in the household. As children are recognized as important persuaders in that process and as they may accompany their mothers to buy the family food, advertising is also targeted at them. Recent studies of food advertising in South Africa show the need of advertisers to monitor social changes because food advertising, like advertising in general, reflects social and cultural trends, values, and attitudes. Cultural differences are also reflected in advertising. Chinese television advertisements tend to signify family values, tradition, and technology, whereas themes in American advertisements tend to symbolize the importance of enjoyment, cost savings, and individualism. With the emergence of global culture, specific values such as global cosmopolitanism and modernity (often symbolized by the hamburger) will be spread around the world.

Food advertising reflects changing food tastes, diet, and dietary habits. The extent of the references to nutrition, health claims, and weight loss has altered in advertisements in recent decades. Research has indicated that in the United States from the 1960s to the 1980s there was an increase in references to health and weight loss in advertisements for hot and cold cereals, bread and cake mixes, frozen and pre-prepared entrees, peanut butter, canned and instant dry soup, and carbonated beverages in a range of women's magazines. There was a significant rise in health claims in the 1980s, higher than in the 1960s, and the percentage of diet claims that appeared in food advertisements in the 1980s was significantly higher than the percentage reported in the 1960s and 1970s. At the same time, between 1960 and 1980,

there were substantial decreases in claims of quality, taste, status, and consumer satisfaction. These may have resulted from changes in women's consumption and dieting behavior and the increased demand for food that is low in calories but high in nutrition. Concerns about increasing prevalence of obesity in the United States and campaigns against fast-food artificiality—both within the United States and beyond—will likely influence food advertising.

### Brand Names

Central to the advertising of food is the promotion of brand names and trade names that distinguish between one manufacturer's product and that of another. As the survival of these names depends on advertising, some brands and trade names have large advertising budgets allocated to them so that they can maintain their status as products and their place in the marketplace. Brands and trade names arose in the nineteenth century as a response to increased production and the need to efficiently and effectively market products. Brand names started to be promoted in the 1870s, after which their use spread quickly. Significant increases were especially noted in the early twentieth century. Even after they were rapidly adopted, the extent of their use varied geographically and throughout time. During World War II, when widespread restrictions caused materials and food shortages, brand names were abandoned in Europe and were replaced by utility products. They came into operation again once peacetime conditions were restored. In some cases this was not until well after all controls on food and other raw products were lifted. Especially developed in Western Europe, brand names were, however, prohibited in Eastern Europe.

Brand names and trademarks are consciously devised by manufacturers. They are based on existing names, mainly personal names or words, or a combination of the two; few have no recognizable origin. The most common are word names that include personal names of manufacturers such as Nestlé (confectionery manufacturer) and Campbell's (the soup manufacturer), names of food-chain stores (Safeway), and the names of food products such as Mother's Pride (bread). Arbitrary names include Saxa table salt. Names often have an association with prestige and a range of desirable attributes, such as quality (Ambrosia rice pudding); wholesomeness (Eden Vale dairy products, Just Juice tropical fruit juices, and Lean Cuisine low-calorie frozen foods); and nutritional value (Marathon confectionery bars). Other names describe ingredients, as with Coca-Cola, a drink made from coca leaves and cola nuts, and Bovril, a drink of concentrated essence of beef.

Each brand name has a number of functions: it ensures consistency and quality; it has a personality that makes the consumers identify with the product; it is a social and cultural marker that helps the consumers to identify who they are and the social group they belong to; it

allows the consumers to gain esteem within their consumer group. These values or aspects of them are reflected in advertising campaigns and advertisements.

Because of the importance of brands and trademarks in identifying foods and other products, they have become legally protected. The first protective legislation in the United States was passed by Congress in 1870. It was altered with different juridical rulings and received its final codification in 1905. Legislation has also been introduced throughout the world. In Britain it has included the Trade Marks Act of 1938.

Food advertisements use a range of appeals to promote a product. Rational appeals tend to be used for healthy foods. Emotional appeals, which are more likely to be remembered, are used for a range of products that includes fun products, or “sin foods,” such as candy or desserts. Taste claims are especially important. Products are compared with similar products in side-by-side tests that point out the qualities their competition does not have (for example, the “Pepsi challenge”); these tests distinguish the product from its competitors by the ways in which it is beneficial to the consumer or puts the consumer at an advantage over those who do not use the product. Further, these tests suggest that the product is like an advertised brand in some way; they refer to the competition, state that the brand is at least as good as any other in a set, and they use experts to endorse the quality, taste, or value of the product so that it is given a heightened status. Nutritional claims are used particularly in advertisements for foods that benefit health and have health-giving qualities. Such claims may state that a product is “low” or reduced in calories, that it is “cholesterol-free” or has “reduced cholesterol”; food and drinks may be “lite” to distinguish them from standard foods. In the United States and some other countries, there are regulations governing the allowable fat content in foods billed as “low fat” and “reduced fat.”

Especially for branded foods, advertisements often use slogans to help the consumer remember the product. They link the product and its function. For many years, the slogan for the Mars candy bar has suggested that it gives the consumer energy to undertake a range of activities throughout the day: “A Mars a day helps you work, rest, and play.” The slogan “Bridge that gap with Cadbury’s Snack” suggested that the biscuit could be eaten to fill in the gap between meals.

### Celebrity Endorsements

Food advertisers use a range of figures who enjoy public recognition to endorse or act as spokespeople for a product and recommend it to the public. Especially after 1920 advertisers were aware of the relationship between popular culture idols and their audiences. Important early endorsers included movie stars and popular entertainers. The list was later extended to include television stars and individuals from occupations such as politics, sports, the

“And now, a word from our sponsor.” If radio stars George Burns and Gracie Allen endorsed Spam, it had to be good. (“Spam” has since become a derogatory term for another kind of advertisement, in the form of unwanted e-mail.) COURTESY OF THE ADVERTISING ARCHIVE LTD.

arts, and business. In an endorsement, an endorser makes the product familiar to the public. It can be done in a number of ways: explicitly (“I endorse the product”); implicitly (“I use this product”); imperatively (“You should use the product”); and copresently (where the endorser appears with the product). In an endorsement, celebrities transfer meaning from themselves (their values, status, class, gender, age, personality, and lifestyle) to the product, and through it, to the consumer. Through that process, people consume a product that is associated with the star and their star image. Celebrities are chosen to represent values that are embodied in the product they endorse. The comedian Bill Cosby endorsed the soft drink Coca-Cola. Although there is a close relationship between the star and the product, not all star and product relations have successfully increased product sales. John Houseman failed as an endorser for McDonald’s although he had been successful in other endorsement campaigns. Endorsements fail when they do not succeed

in transferring meaning: the values between the celebrity and the product are too wide for the meaning to move between the endorser and the product.

### Controls on Advertising

All food advertising is governed by a number of controls. Some of these regulate advertising in general. Defamatory statements, false representations, offers to contract, incitements to crime, contempt of court, breach of copyright, and infringement of trademarks are covered by legislation that governs libel, deceit, contracts, crime, and the infringements of rights. More specifically, in Britain in the late nineteenth and early twentieth centuries, legislation included the Indecent Advertisements Act of 1889 and the Advertisements Regulation Act of 1907, which was amended in 1925. At a wider level, the general law also affects all advertisements.

Codes of advertising have been issued as guidelines to advertisers. In the United States from 1911, steps were taken to provide codes of practice. Early codes were issued by the Associated Advertising Clubs of the World. Guidelines have also been expressed in a number of codes such as the British Code of Advertising. The Code, issued in 1979, embodies the principles that "all advertisements should be legal, decent, honest and truthful"; "all advertisements should be prepared with a sense of responsibility both to the consumer and to society"; and "all advertisements should conform to the principles of fair competition as generally accepted in business." The codes contain specific rules that govern food advertising, packaging, and labeling of foodstuffs. They define how foods can be described and the nature and scope of the nutritional information presented on the packaging. Nutritional information has become increasingly widespread in the European Community and the United States. In Britain, sections of the Customs and Excise Act 1952 prohibit misdescription in advertisements of beer and spirits. The Food and Drugs Act (as subsequently amended) contains certain requirements as to advertising and labeling of food. A number of regulations deal specifically with the representation of food claims. Diet foods are particularly regulated, for example in the 1970 British Labeling of Food Regulations, which require that "where a claim is made in an advertisement or on a label that any food is an aid to slimming, it must be substantiated, and a statement must be included that the food cannot aid slimming except as part of a diet in which the total intake of calories is controlled, whether by calorie counting, low carbohydrate/high protein or other means." Other aspects of "slimming" that are regulated include diet plans, aids to dieting, foods, appetite depressants, and weight-loss products in general. Parallel regulations and advertising codes have also been introduced in other countries such as the United States. In the 1980s in the United States, consumer protection remained the major rationale for the regulation of advertising. Other forces included new media technologies, issues of privacy and fairness, environ-

mentalism, religion, changing economic conditions, the deregulation movement, and foreign regulatory initiatives made necessary by international trade agreements.

## AFRICA.

*This entry includes four subentries:*

Central Africa  
East Africa  
North Africa  
West Africa

### CENTRAL AFRICA

Central Africa is broadly defined as the Congo River basin, plus adjoining areas in equatorial Atlantic-coast Africa. It comprises all (or parts) of Burundi, Cameroon, Central African Republic, Chad, Congo (Brazzaville), Congo (Kinshasa), Equatorial Guinea, Gabon, and Rwanda. (The list varies from one authority to another.) Where it meets Africa's Northern and Southern regions there are grassy savannas and veldts, at its juncture with East Africa, mountain ranges and great lakes. Central Africa's dominant feature, however, is equatorial rain-forest and numerous rivers and swamps.

Central African gastronomy is the least known of any other similarly sized region, due partly to lack of documentation, as most Central African languages were not written down until the colonial era of the eighteenth and nineteenth centuries. Slaves, ivory, rubber, and minerals, not the region's cuisine, interested most non-Africans (Europeans and Arabs) who went there.

#### The First Inhabitants

The equatorial forest of Central Africa has remained unchanged by the cycles of global warming and cooling that, over tens of thousands of years, have frozen Europe and dried the Sahara. It is the home of the descendents of the first human inhabitants of the region: the Mbuti, Aka, and Efe people of the Ituri forest, the Twa of the Lake Kivu region, and related peoples. (Collectively these groups are called "Pygmy," a term that has fallen from favor, yet no other collective appellation has emerged.) When the forest people first arrived in Central Africa is unknown. One of them, taken to Egypt by an expedition that explored the area south of Egypt, is mentioned in Egyptian texts from between 2255 to 2152 B.C.E.

Unmatched in their ability to survive in the forest, the forest people live, for the most part, as they have for millennia. Using bows and poison-tipped arrows, nets, or spears—sometimes with the aid of Basenji dogs—the men hunt everything from antelope and birds to elephants and hippopotamuses. The women gather berries, fruits, insects, leaves, mushrooms, nuts, and roots. To move from campsite to campsite, they must have lightweight household goods. The most basic cooking methods are appropriate: roasting, smoking, and drying meats, and stewing meats and vegetables. When they kill a large animal, it is easier for them to move to the meat than vice-versa. The Mbuti brew a beverage called "liko" from berries, herbs, and kola nuts. A favorite sweet is wild honey.

#### The Arrival of Agriculture and New Foods

Over the past two millennia, because they have had increasing contact with other Africans—trading with them (exchanging forest products for agricultural foods and manufactured goods) and partially adopting their languages and cultures—forest peoples also eat foods such as the leaves and tubers of cassava (manioc, *Manihot esculenta*), rice, beans, peanuts, and tomatoes, from which they prepare stews and sauces.

The "other Africans" are the present-day Kongo, Mongo, Luba, Bwaka, Kwango, Lulua, Lunda, Kasai, Douala, and related peoples (there are hundreds of Central African ethnic groups). Collectively, they are called Bantu speakers, as their languages are part of the Bantu language group. (Bantu is a linguistic designation, not a racial one, and can be misleading because many people who speak Bantu languages are not related to the original speakers.) Bantu speakers began migrating into Central Africa from around the Nigeria-Cameroon border approximately two to three thousand years ago.

Over the course of several centuries, the population of Bantu speakers increased and they spread throughout Central and Southern Africa because they did two things that the original forest inhabitants did not: they worked iron into tools and weapons (Central Africa completely skipped the Bronze Age), and they obtained food from agriculture and, to a lesser extent, domesticated animals. (Diseases carried by Africa's tsetse fly prevent keeping livestock.) The forest people had lived in and with the forest; the Bantu speakers turned forests into farms. However, food obtained by hunting and gathering remained

(and continues to be) an important part of their diet. In many Bantu languages, the words for “animal” and “meat” come from the same root, attesting to the close association of the two.

Contributing to Bantu expansion were Asian food crops that arrived in Africa at roughly the same time (circa the first century C.E.): bananas, plantain, and tuber crops such as yam and taro, which have been staple foods ever

since. African varieties of millet, rice, sorghum, other yam species, and okra were also cultivated. Agricultural production of these high-yield crops enabled the Bantu speakers to increase their population dramatically, and they are now the overwhelming majority. More increases in population, and further migrations, occurred after the 1500s, when crops from the Americas were introduced to Africa: cassava, corn (maize), peanuts (groundnuts), tomatoes, chili peppers, sweet potatoes, papaya, pineapple, and avocado.

Central Africans have practiced swidden (slash-and-burn) agriculture for centuries. Men clear the forest and prepare the ground, but women do the rest of the work on the “plantation” or “shamba” (cultivated fields): planting, weeding, and harvesting.

Not every crop grown in Africa has been imported, but foreign crops have replaced many indigenous crops. The American peanut (*Arachis hypogaea*) replaced the Bambara groundnut (*Vigna subterranea*); Asian rice (*Oryza sativa*) replaced African rice (*Oryza glaberrima*); the chili pepper (*Capsicum*) replaced melegueta pepper (grains of paradise, *Aframomum melegueta*); and onions and garlic replaced various herbs and roots. Even the salt changed. In the Central African interior, the only salt once widely available came from various plants. It was obtained by burning leaves or bark, soaking the ashes in water, and evaporating the water in pans. Some cooks still use *sel indigène* (indigenous salt) or substitute baking soda to approximate its taste. Thus, foodways have not been static throughout history, and the larder was stocked for contemporary Central African cuisine.

### Stews and Starches

Stewing has probably been the most common cooking method in Central Africa for centuries. Central African kitchens are located apart from the living and sleeping quarters. In each a large pot or cauldron for making stews rests on three stones above a wood fire. These dishes are usually simple, made with only a few ingredients. Stews are usually thickened with African oil palm fruit or crushed peanuts, but other thickeners are also used: crushed seeds of *Cucurbitaceae* (gourds, melons, and pumpkins), known by the West African name, *egusi*, and called *mbika* in Central Africa; crushed seed kernels of the *mangue sauvage* (wild mango) fruit (*Irvingia gabonensis*), called *odika*, *dika*, or *etima*; and okra, which is called *ngumbo*.

It is difficult to know whether to call these dishes stews, soups, or sauces. Part of the confusion is that they are eaten with a starchy staple dish. Many Africans believe that the only real meal is one that combines a stew or sauce with a starch. In West Africa, *fufu* is boiled pounded yam or plantain. In Central Africa the same process, pounding with mortar and pestle (often made from an entire tree trunk and limb), followed by boiling

and vigorous stirring or steaming, is used to make similar starchy staples. The word *fufu* refers to a dish made by boiling any sort of flour: maize, sorghum, millet, or cassava. (Cassava flour is dried ground cassava tuber; tapioca is the same thing.) These foods, called “dumplings” or “porridges” by English speakers, are comparable to East Africa’s *ugali* and Southern Africa’s *nsima*, or *sadza*. Another *fufu*-like staple is prepared by soaking cassava tubers in water for a few days, pounding them, then wrapping the resulting pulp in leaves and steaming it. The soaking and steaming breaks down poisonous cyanide compounds in the tubers. The finished product is called *kwanga*, *chickwangué*, *bobolo*, *mboung* or *placali* (usually ball-shaped), or *baton de manioc* (manioc stick). Women prepare *kwanga* in large batches to sell, ready-to-eat, in the market. They make the flour-based dumplings and porridges, as needed, in the home. These foods are heavy and thick, much more so than mashed potatoes. Many non-Africans do not like them at first, but they often make the mistake of taking a bite of such starches without sauce. Africans eat these bland starchy foods with a stew or sauce, usually heavily seasoned. As with West African *fufu*, a bite-sized piece of the *kwanga* (or something similar) is pulled off, dipped into the stew, then eaten. Rice and European-style bread, especially French baguettes, are also eaten with stew.

### Greens

One distinguishing characteristic of Central African cooking is the use of edible leaves, which Americans call “greens.” Indeed, the greens of the southeastern United States—collard greens, kale, and mustard greens—have their roots in Africa. In French-speaking Central Africa these are commonly called “feuilles” (leaves). It is hard to overstate the amount and variety of greens consumed. Oftentimes greens are the main ingredient in the daily stew, cooked with only a little onion, hot pepper, meat, fish, or oil for flavoring. Some of the greens consumed in Central Africa are bitterleaf, cassava, okra, pumpkin, sorrel, sweet potato, and taro. People cultivate greens and gather them from the wild. Cassava leaves (“feuilles de manioc”) are the most commonly farmed. In many tropical areas of the world cassava is grown primarily for its tubers, but Africans have a long tradition of eating both the leaves and the tubers of this plant. *Gnetum africanum*, called *okok*, *koko*, or *eru*, is a variety of greens that grows wild. Before cooking, women pound greens in a mortar and pestle, or roll them like giant cigars and use a sharp knife to shred them finely. *Saka-saka*, or *pondou*, is a dish made from cassava leaves, onion, and a bit of dried fish. *Saka-madesu* is cassava leaves cooked with beans. Another recipe, variations of which are found all over sub-Saharan Africa, calls for greens to be cooked with tomato, onion, and mashed peanuts. Other greens dishes are made with tomato, onion, chili pepper, and fresh, salted, or smoked fish, or even canned sardines. Greens and meat are also often cooked together.

## CENTRAL AFRICAN CUISINE

Richard Francis Burton, the nineteenth-century traveler and writer, is famous for his efforts to discover the source of the Nile and his account of a visit to Mecca. He could have been describing Central African cuisine when he described the food he encountered in Bonny River, in present-day Nigeria, near the boundary between Central Africa and West Africa. In the first sentence, Burton gives the “Anglicé” (English) names for African foods: “obeoka” = fowl; “nda” = fish; “fufu” = mashed yam; “fula” = soup; and “tomeneru” = tombo, or palm wine.

breakfast is served. It is a little dinner, ordinarily consisting of obeoka, nda, fufu, fula and tomeneru,—Anglicé, fowl, fish, mashed yam, soup i.e. (the liquid in which stews have been boiled), and tombo, or palm-wine the latter however, hard, tasting like soapsuds, and very intoxicating. The cooking is excellent, when English dishes are not attempted. . . . Most of the dishes are boiled, and copiously peppered with cayenne and green chili pods to induce thirst. There are many savoury messes of heterogeneous compounds, fish, fresh and dried, oysters, clams, and cockles, poultry, goat and deer, salt beef or ship’s pork, yams, plantains and palm oil. Smoked shrimps are pounded in a wooden pestle and mortar, with mashed yam for consistency, and are put into the soup like forcemeat balls.

A dinner similar to breakfast is eaten at 4 to 5 P.M. Soup and stews are the favorite menu, and mashed yam acts as a substitute for bread. It is also made into a spoon by a deep impression of the thumb, and thus it carries a thimblefull of soup with every mouthful of yam. The evening is passed with the aid of music, chatting with the women, and playing with the children.

SOURCE: Richard F. Burton. *Wanderings in West Africa*. Vol. 2. New York: Dover, 1991, p. 289.

### Red Palm Oil

Another distinguishing characteristic of Central African cuisine is the use of red palm oil, obtained from the fruit of the African oil palm, *Elaeis guineensis* (not to be confused with the clear oil pressed from the hard kernel). Reddish and thick, it has a distinctive flavor for which there is no substitute. Women make red palm oil, or palm butter, at home by boiling and hand-squeezing fresh palm nuts. The oily pulp is cooked with chicken, onion, tomato, okra, garlic, or sorrel leaves, and chili pepper to produce a stew called *moambé* or *poulet nyembwe* (also *gnemboue*). *Moambé* is also made with other meats. This is one of many Central African dishes related to West

African counterparts, in this case the West African palm oil chop, though the Central African versions tend to be simpler and made with fewer ingredients. Outside of Africa, canned palm soup base (also called *sauce graine*, *noix de palme*, or cream of palm fruit) can be used.

### Peanuts

Peanuts are roasted and eaten as snacks, but they are used more interestingly in stews and sauces. The chicken-groundnut stew—made from chicken, peanuts, tomato, onion, and chili pepper—is common in Central Africa, as it is throughout sub-Saharan Africa. Peanut sauces are served with roasted meats or fried fish, or boiled yams, sweet potatoes, or rice. Greens are cooked in groundnut sauce; meat, fish, or fowl can be added to produce a variety of stews.

As with red palm oil, there are similarities between the ways peanuts are used in Central African and West African cooking. West Africa’s groundnut chop is similar to the *muamba nsusu* (chicken soup) of the Kongo people, though the Central African version—made with chicken, onion, palm oil, tomato, ground peanuts, and hot chili pepper—is the less elaborate of the two. It is also the source of the peanut soups served in colonial North America. Many Americans mistakenly believe that peanuts are indigenous to Africa and were brought by Africans to the United States. After all, an American name for the peanut, “goober,” comes from its Kongo name, “nguba.” Africans may have brought peanuts to North America, but in fact they are indigenous to South America and were introduced to Africa in the early 1500s. (Diffusionist historians, who posit that Africans sailed between Africa and the Americas before Columbus, challenge this.) Africans quickly adopted the American peanut because it resembles an indigenous African plant, the Bambara groundnut. Like the American peanut, the seeds (legumes) of the Bambara groundnut grow and ripen underground. Africans used the Bambara groundnut in the same way they use the peanut. For various reasons, farmers and consumers preferred the American peanut, and the Bambara groundnut is a nearly forgotten crop.

### Banana Leaves

An interesting Central African cooking method is steaming or grilling food wrapped in packets fashioned from the leaves of banana trees or other plants. This is an old cooking method, predating the use of iron, maybe even clay cooking pots. It is very practical when camping or traveling as it eliminates the need to carry pots, and the leaves can also be used as plates and bowls.

Certain leaves are especially favored because they give a particular flavor to food. *Kwanga*, for example, is wrapped in leaf packets before its final steaming. *Maboké* (singular *liboké*, also called *ajomba* or *jomba*)—leaf-wrapped packets of meat or fish, with onion, tomato, maybe okra, seasoned with lemon juice or hot chili pepper—are grilled over hot coals or steamed in a pot. Crushed peanuts, or *mbika*, are

## DIFFUSIONISM: DID ANCIENT AFRICANS SAIL TO THE AMERICAS?

Who came to the Americas, and when, is a subject of debate between scholars who believe that ancient peoples, including Africans, sailed the world's oceans to the Americas, and others who say there is no evidence of pre-Columbian contact between the Old World and the New.

The traditional view is that Native Americans, after migrating into North America from Asia (via Beringia) tens of thousands of years ago, gradually spread south and east, developing their civilizations without input from the Old World until Christopher Columbus (or Leif Erickson) sailed across the Atlantic in recent historical times. Likewise, the traditional view holds that plants, foods, and cultural artifacts of the Western Hemisphere did not reach the Old World (and vice versa) until the post-1492 era of European conquest.

The diffusionist view of history challenges traditional scholarship. Diffusionist historians maintain that, in addition to the Asian incursion across Beringia, there were many transoceanic contacts between the Old World and the New, beginning in ancient times and continuing until the era of Columbian exploration. Supporting the diffusionist position is the life's work of Thor Heyerdahl, who proved that it is possible to sail great distances using ancient shipbuilding and navigational technology (in 1947 sailing from Peru to eastern Polynesia and in 1969 sailing from North Africa to Barbados on balsam rafts).

Further support comes both from the existence of Old World artifacts in the New World (and vice versa) that evidently predate the Columbian era and from oral history. Opponents of diffusionism argue that because ancient peoples could have sailed across the ocean is no proof that they actually did, that other evidence is either coincidental, occurred after Columbus, or has not been correctly dated, and that oral history is only myth. Complicating the debate are charges of prejudice from both sides.

As concerns Africa, diffusionist scholars believe that Egyptians and Phoenicians sailed to the New World in ancient times, as did Malians (of the former Sudanese Republic) in medieval times, observing that the design of Mesoamerican pyramids is strikingly similar to those found in Egypt and that Mesoamerican statues depict African explorers. If regular trade relations between Africa and the Americas are assumed, American plants such as cassava, chili, maize, tomato, and tobacco may have been known in Africa hundreds of years before they were introduced by Europeans. Likewise, African foodways may have been brought to the Americas before Columbus. It has been a quarter century since the publication of the important (though by no means only) work in this field: *They Came before Columbus* by Ivan Van Sertima. More research and evidence are needed before this debate can be resolved.

sometimes included in the packets. Filling the leaf packets with mashed beans (such as black-eyed peas) and sautéed peppers, then steaming, produces *koki* (also called *ekoki* or *gâteau de haricots*).

### Meat, Fish, and Fowl

Generally, people in Central Africa eat meat, fish, or fowl whenever possible. Every village has domesticated chickens (or guinea fowl) and goats. Wild game, *viande de brousse* or bushmeat, is very common: antelope, birds, buffalo, crocodiles, fish, monkeys, pangolins, wild boars, and many other species are hunted. Almost every type of wildlife—from insects to primates—is hunted and eaten in Africa, though individual ethnic groups have their own traditions regarding what is edible and what is not. Some will eat snake meat, for example, while others will not. There are many traditional beliefs concerning who should eat certain foods and who should not: for example, a certain food may be reserved for men because it is believed that women who eat it cannot become pregnant or will suffer other ill effects. Women in the Odzala re-

gion of the Congo Republic do not eat gorilla meat, fearing that doing so would cause their husbands to become as brutal as gorillas.

Killing a large animal means a feast for everyone. Where there is no refrigeration, drying, salting, or smoking meat or fish is used to preserve it. All sorts of bushmeat—antelope, buffalo, crocodiles, hippopotamuses—as well as fish, are preserved in this way. When meat is not plentiful, a small amount is added to stews for flavor.

### Beverages, Snacks, and Desserts

Bottled beer and soft drinks, sometimes unrefrigerated, are available throughout Central Africa. Traditional beverages include *vin de palme* (palm wine), self-fermented palm tree sap. Beer is made from corn, millet, plantains, and sorghum. Cassava, yam, or plantain porridges are thinned with water to make breakfast beverages, weaning foods for infants, and nutritious drinks for convalescents. Coffee and tea are also popular beverages. Central Africans are great snackers. Vendors selling hot beignets (French-style doughnuts), fried plantain, grilled corn-on-the-cob,

## BUSHMEAT

“Bushmeat” (or, in French, *viande de brousse*) is wild game, meat taken from wild animals of the African forest or savannah, often called “the bush.” Bushmeat can come from nearly any species of wildlife including antelope, boar, buffalo, cane rat, chimpanzee, crocodile, elephant, gorilla, hippopotamus, monkey, pangolin, and porcupine, as well as various birds and reptiles. Each ethnic group has its own traditions and taboos concerning which animals can be eaten and which cannot, but hunting wild animals for meat (and other products) is an extremely old tradition, predating the development of agriculture. Certain African peoples are herders and farmers, but in parts of Africa afflicted with the tsetse fly or poor forest soil and climate the food produced from domesticated animals and plants may not be sufficient to replace what hunting can provide.

Traditionally, hunting is a sign of manhood in much of Africa, and it is considered “men’s work,” whereas women are expected to tend the fields and care for children. Also, as is the case with horsemeat in France, people believe that certain types of bushmeat are especially healthful or possess curative properties. Bushmeat is an important protein source in the diet of rural people; when they do not eat it, the money they earn from selling it is a significant portion of their income.

Like loss of habitat and poaching animals only for their hides or tusks (leaving the meat for vultures and insects), hunting for bushmeat threatens African wild-

life with extinction. In the past, human populations were small and hunting was less of a threat to the survival of any given animal species; also, certain types of bushmeat were reserved only for the chief. Modern times have brought larger populations, the development of urban elites willing to pay high prices for favorite bushmeat, roads connecting rural villages to large cities, and airports connecting Africa to the outside world. The resultant commercial trade in bushmeat has caused many ecologists to be concerned about the possible extinction of certain species. As populations and incomes grow, the demand for bushmeat is likely to increase. Logging activities in virgin forests, which bring roads and trucks to undeveloped areas, have the unintended consequence of connecting rural hunters to urban markets, and many logging workers supplement their income by being bushmeat middlemen, in addition to consuming bushmeat themselves. Hunting is generally a *laissez-faire* enterprise, and national and international regulations concerning wildlife and hunting are usually ignored. Any awareness among rural people of the need to preserve wildlife is outweighed by their need for food and money. It is easy for people outside of Africa to criticize their customs and actions, but it should be remembered that Africans are not the first to hunt an animal to extinction, as the history of aurochs, dodo birds, passenger pigeons, and other species makes clear.

kola nuts, brochettes (shish kabobs), roasted peanuts, soft drinks, and various fruits are seen on urban streets and near bus and taxi stops and train depots.

Generally, the traditional Central African meal is not followed by a dessert course. Sweet snacks include sugar cane, fruits, and European-style candies.

### Food and Eating Customs

Traditionally, women and girls do the cooking. Men and guests eat apart from women and children. Oftentimes, breakfast is leftovers from the prior evening, a snack is eaten during the day, and a large meal is eaten in the early afternoon. People have adopted the Western custom of three meals a day, with certain foods, like bread and coffee, eaten primarily for breakfast.

Many other Western influences are seen in Central African cuisine. In urban areas, much of the diet of well-to-do consumers would be familiar to any European or American: hamburgers, pizza, and ice cream. Even in small towns, people can obtain imported spaghetti, canned

meats and vegetables, and L’Arome Maggi® bouillon cubes (which seem to be essential for cooking). In both urban and rural areas, farmers and traders sell locally produced foodstuffs in open-air markets. Cities also have sprawling markets that are busy from sunrise until late at night, while small-town markets may be open only one day a week. In rural areas, households sell farm produce and bushmeat on the roadside, displaying it on a barrel or table. It is common to see urban dwellers lugging home large sacks of food after a visit to the countryside.

### Festivals and Celebrations

People in Central Africa celebrate Christmas, New Year’s, the end of the school year, and marriage with parties and family gatherings. African religious festivals and ceremonies, however, vary from one group to another. Many ethnic groups celebrate the *nkanda* or *mukanda*, which are initiations for young people. They signify the beginning of adulthood and may include ceremonial songs and dances, special teachings given in seclusion, in-

duction to secret societies, circumcision, and symbolic death and rebirth. There may be special foods that are consumed only on these occasions, and there is always an emphasis on having plenty of food, preparing elaborate dishes, and, perhaps, obtaining imported food and drink. The African-influenced Christian Kimbanguist Church prohibits eating pork or monkey or drinking alcohol.

Central African cuisine will no doubt continue to adapt to new circumstances and adopt new influences. More attention should be paid to this relatively little-known area.

## EAST AFRICA

East Africa comprises ten countries: Tanzania, Burundi, Rwanda, Uganda, Sudan, Ethiopia, Eritrea, Djibouti, Somalia, and Kenya. Among residents of this region, the name Eastern Africa usually refers to these ten countries, while the name East Africa means the political region comprising Kenya, Uganda, and Tanzania. In this article East Africa refers exclusively to the ten countries mentioned. This region covers an area of about 2.3 million square miles and in 2002 had a population of about 190 million people. East Africa has over 500 linguistically distinct communities, which fall into five distinct groups: the Bantu, Nilotic, Cushitic, Sudanic, and Semitic peoples. This area is also home to many people of Arabian, Indian, and European origin.

Besides being ethnically diverse, East Africa is extremely geographically diverse. Bounded to the east by the Red Sea and the Indian Ocean, the land rises (often on a plateau) to the Ethiopian and East African highlands, which contain five of the highest mountain peaks in Africa, such as Mount Kilimanjaro. Dividing these highlands is the Great Rift Valley. In East Africa, where it forms two arms (eastern and western), the Great Rift Valley has a series of lakes on its floor and all around it. All these geographical features have a heavy influence on the climate of the region, which has extremes of temperatures, humidity, and precipitation. Most of the lowland areas are hot and dry. Djibouti, regarded as the warmest city in the world, has a mean annual temperature of 86°F. Seventy-five percent of the region is either arid or semiarid, the Horn of Africa and upper half of Sudan being extremely arid. Rainfall is erratic, and there is a high incidence of famine in the region. The highlands are generally cooler and receive more precipitation. Near the equator, the rainfall has two peaks per year.

Much of the agriculture is concentrated in the highlands and around the Great Lakes of East Africa, and these areas contain the highest concentration of people. Ninety percent of East African people are employed in agriculture and livestock, with the highlands being used mainly for crop production and the dryer lowlands for animal production.

The great diversity in East Africa's climate, physical features, and ethnic groups is reflected in its food

culture. This culture is further enriched by the long history of interactions with people from other continents, especially the Arabian and Indian peninsulas.

### Introduction to East African Food Culture

Perhaps some of the best and oldest evidence of what human ancestors ate can be found in Ologesailie, a historical site on the floor of the Great Eastern Rift Valley that is about 40 miles (66 kilometers) south of Nairobi, Kenya. This hot, dusty site located in a semidesert scrub was once (during the Stone Age) a lake in a lush environment that teemed with wildlife. At this site, thousands of wedgelike stone tools (handaxes, cleavers, scrapers, knives) of varying sizes litter the ground. These were the tools that human ancestors fashioned skillfully and used to dig for food and to tear up their kill, probably antelopes, giraffes, and other ungulates that came to drink water at the shores of this lake.

About five thousand years ago, much of East Africa was occupied by hunters and gatherers, commonly referred to as *ndorobo*. Although a few of these people still exist, most of these groups were assimilated by later migrants and therefore lost their identity, including their food culture. With spears, snares, and poisoned arrows they hunted big and small game—from rabbits and dik-diks to buffalo, giraffes, and elephants, and in some cases stray cat and dog families, as well. The practice of hunting still exists in East Africa, but only at low levels since it is forbidden in most countries. Gathering wild foods—such as fruits, nuts, tubers, honey, grasshoppers, caterpillars, termites, eggs, and some birds—was also an important way of acquiring food for ancestors who lived in this region. Today the contribution of gathering is less significant but many aspects of it remain. For example, during the rain season, the flying reproductive forms of termites (*tsiswa* in Luhya) emerge from termite mounds. These are trapped, dried or roasted, and eaten or preserved in honey, or used as a snack and occasionally in sauce. A variety of caterpillars (*maungu* in Giriama) are also harvested and eaten. Wild birds that resemble a small chicken, such as *tsisindu* in Luhya or *aluru* in Luo, are considered delicacies. Tubers and nuts obtained from the ground are a source of energy and water among people who herd livestock. The Maasai potato (*oloiropiji* or *Ipomoea longituba*), which is characterized by a flat taste, may weigh up to nine pounds and contains enough water to last a herder a whole day.

The key animals that are raised in East Africa are cattle, sheep, goats, camels, pigs, and donkeys. Cattle, which are the most important of these, were introduced into the region from North Africa in 3000–2000 B.C.E. and are the economic base for livestock keepers/pastoralists who live in drier regions. The foods of livestock-raising groups are animal based, with milk products being by far the most important. Milk is obtained from camels, cows, goats, and occasionally sheep. It is taken fresh or is fermented in containers—mainly gourds

(*kuat* in Sudan or *kibuyu* in Swahili) or hollowed-out wood, as is the case with many pastoralists to the north and east of the region. The milk is then churned to make butter and sour milk (*rob* in Arabic or *chechiro* in Dinka), which are very popular foods in southern Sudan and among pastoralists. A variety of sticks are burned in such milk containers to disinfect and to impart a nice flavor to the milk. A popular tree for this purpose is the African olive (*oloirien* in Maasai or *Olea europaea* ssp. *africana*). The Somali community adds the aromatic hoary basil (*Ocimum americanum*) to milk as a flavoring. Butter, which was a major item of barter trade in the past, is used in preparing other foods or is mixed with other foods to add flavor. Milk, which people often drink sweetened with sugar, may be used as an accompaniment for *ugali* or *sima* (*asida* in Sudan), which is a type of stiff porridge.

To most pastoralists, fresh blood obtained by darting the jugular vein of an animal (usually a cow) is an important food, especially during times of food shortage. Blood is normally mixed with milk and stirred vigorously into a uniform brown mixture. Among the Somali, fresh blood from goat (*diik*) is recommended for women after delivering babies. A more common use of blood is stuffing it in the intestines of an animal (with spices) and cooking or roasting them. This dish, called *mutura*, is usually served in the form of large sausagelike segments. Bone soup is also popular among pastoralists. Plant parts such as bark of *olkiloriti* (Maasai for *Acacia nilotica*) are used both as a flavoring for soup and as medicine. Pork is not allowed in most of Ethiopia and among the Muslim communities, and is not tolerable in many communities. Its consumption, however, is well established in fast foods.

Agriculture is, by far, the most important production system in East Africa. Agriculture in Eastern Africa was pioneered by Cushitic speakers from the Ethiopian highlands. Other cultivators came in from the south, west (Bantu), and northwest (Nilotes). The earliest food crops of most agriculturalists included sorghum, finger and pearl millets, hyacinth (lablab) beans, Bambara groundnuts, bottle gourds, cowpeas, and yams. East African farmers eventually acquired a number of Asian crops such as banana, cocoyams, and sugar cane, as well as crops from South America, such as pumpkins, cassava (manioc), groundnut, and sweet potato. In the years following the explorations of Christopher Columbus, East Africa began to receive American crops such as maize, peanuts (groundnuts), kidney beans, and potatoes, as well as European cabbage and kales. Such foods quickly spread in popularity during the colonization era (c. 1850–1960) and became the most important foods in the region. In spite of these more recent introductions, many cultural groups retained their traditional foods, but with modified preparations.

### Common Foods of the East African Peoples

Over the years, East African communities have developed and adopted specific recipes. In southern Sudan the more

common foods are milk (sour or fresh), *kisira* (a type of pancake), rice, *asida* (*ugali*, or stiff porridge), and fish. In Ethiopia, typical foods would be *injera/firfir*, *kichab* (spiced pancake), *dabo* (bread), and *bula* (*ensete*, or stiff porridge). These are normally served with a variety of hot sauces (*wat*, or *watt*) on one large tray for the entire family. In Somalia the more common foods include milk (camel and cow), *canjeero* (a type of *enjera*), pasta, *otkac/nyirnyir* (dried meat), *xalwa* (a type of dessert), and *labee* (blood). In Kenya the most common foods include *ugali*, *githeri* (a mixture of maize and a pulse—that is, seeds of legumes, such as chickpeas, lentils, field peas, peanuts), *pilau* (spiced rice cooked with meat), and *chap-ati*. In Tanzania, *wali/pilau* and *makande* (a mixture of maize and beans) are common dishes. In Uganda, a common food is steamed *matooke* (banana) and also sweet potato and cassava products served with groundnut sauce. In Uganda *ugali* is a rather recent dish and is not very popular. In Rwanda and Burundi, beans cooked with vegetables and other starchy foods such as sweet potatoes, cassava, and green bananas are most popular. A type of *ugali* made from cassava—*ubuswage*—is also common.

In the inland part of Kenya, food preparations tend to be simple. Frying with oil and onion is the most popular way of improving food flavor. However, preparations are more complex and time-consuming in coastal parts of Kenya and Tanzania, where the use of coconut as a flavoring is widespread. Consequently, the foods in these regions are tastier than in inland regions. In Sudan some preparations, especially those involving food fermentation, are quite elaborate and may take up to two weeks to complete. In Uganda, steaming food that is wrapped in banana leaves is popular for preparing things such as sweet potatoes, *ugali*, bananas, cassava, vegetables, yams, and cocoyams. Of all the East African countries, Ethiopia seems to have the most elaborate food preparation methods, usually involving fermentation and spicing, especially with hot pepper.

**Maize, sorghum, and millets.** In the last quarter of the twentieth century, maize replaced sorghum as the most important cereal in East Africa. It is common to see people in urban areas fanning a charcoal fire in the streets and roasting fresh soft maize. Passersby buy this roasted maize (*mabindi ya kuchoma*) and eat it as they walk. Green maize is also boiled in water (*amakhaye* in Kisa), with or without the inner covers, and is salted and eaten just like roasted maize. Alternatively, fresh maize is removed from the cob and boiled fresh or when dry (*inete*). Among the Somali, fresh maize (*galeey*) is fried in oil and taken as a snack. Dry maize is fried in sesame oil to make popcorn (*salol*), which is often served with coffee to men as they chew khat (*miraa*).

Another popular East African food is *githeri*. This is basically a boiled mixture of fresh or dry maize with seeds from beans, garden peas, lablab beans, groundnuts, cowpeas, and pigeon peas. *Githeri* may be consumed alone or mixed with leafy greens or stews, especially meat stew.

When *githeri* is cooked with potatoes or cocoyams and occasionally leafy greens (mainly leaves of pumpkin, cocoyams, or Malabar gourd) and mashed, the sticky green substance that results is called *mukimo*. Among the Taita of Kenya, *mukimo* is made by mashing cooked cassava, sweet potatoes, or plantain with leguminous seeds, and it is known as *kimanga* or *shibe*.

*Muthokoi* (*naamis* in Mbulu) is a dish similar to *githeri*, but it is prepared from dry maize that has been processed to remove the tough seed coat (testa). In the Arusha region of Tanzania, cooked maize (*makande*) and rice are mixed with sour milk and served. A dry mashed mixture of maize and beans is mixed with smoked, nearly ripe bananas and mashed. This food, called *mangararu* by the Meru of northern Tanzania (*makukuru* in Swahili), can last for several days.

**Ugali (*sima*).** Probably the most important food in East Africa is *ugali* or *sima* (*asida* in Arabic, *kun* in Dinka, *kawunga* in Baganda, *akaro* in Banyankore, *buro* in Banyoro). *Ugali* is a sticky, moist dish that is made by mixing flour from a starchy food (mainly cereal and usually maize, but it can also be sorghum, finger millet, pearl millet, wheat, and occasionally cassava, or a mixture of any of these) in hot water and cooking as one mixes the substance to a paste that varies in consistency from place to place. *Ugali* by itself has a mild taste. It is usually eaten with one's fingers. It may be eaten with sour fermented milk, a vegetable stew (for example, beans, cowpeas, pigeon pea, green gram), meat stew, green vegetables, chicken, or fish. In the Lake Victoria region, fish is a common accompaniment. The combination of roasted meat (commonly known as *nyama-choma*) and *ugali* is considered a delicacy in beer-drinking places. *Ugali* is very filling and is known for its ability to make people sleepy; hence it is good for the evenings.

*Ugali* made from finger millet (sometimes mixed with sorghum) is popular among the Banyankore, Bakiga, Batoro, and Banyoro of western Uganda. Among the Karimojong of northeast Uganda and the neighboring Turkana of Kenya, a soft type of *ugali* (locally known as *atapa*) is often made from sorghum or pearl millet and is usually taken with sour milk, which may occasionally be mixed with animal blood.

*Ugali* made from cassava is common in the Lake Victoria region and in Burundi (*ubuswage/ubutsima bw'imyumbati*). Large balls of this *ugali* are wrapped in banana leaves (*imitoto*) and stored in a basket. These are picked and served with fish (*ifi*). Among the Lugbara and Madi of northwest Uganda, cassava flour is often mixed with millet or sorghum flour to prepare a type of *ugali* known as *enya* (Lugbara) or *linya* (Madi). The Iteso of Eastern Uganda and neighboring Kenya make a similar type of *ugali*, which is often eaten with groundnut paste.

In Ethiopia's Oromia region, a soft type of *ugali*, locally known as *genffo*, is prepared from wheat or maize flour and is served on a plate. A hole is then made in the

A bounty of colorful, fragrant fruits and vegetables await buyers in this African market. PHOTO BY DAVID K. O'NEIL.

middle and butter and powdered pepper and some salt are added. A more elaborate preparation is that of a breakfast food known as *kijo*. These are balls or lumps of fine, half-fermented maize starch wrapped in maize leaves and cooked by dipping the balls in boiling water. Each ball is given to one person and it is eaten with fresh or sour milk, tea, or coffee.

Another type of *ugali* is *chenga*, which is made from coarsely ground maize. Chenga is usually eaten with sour milk. In southern Sudan, sorghum is used to prepare a type of chenga, which is served with sour milk (*amok*, *chekipiu*), fish (*rech*), or meat (*ring*). This food is served at weddings and special ceremonies surrounding the event of a woman's first menstruation. Among the Kamba of Kenya, cleaned sorghum seeds are boiled with pigeon peas (*ngima ya munyala*). In southern Sudan, millet is also used to prepare a type of chenga known as *dukun* (Arabic) or *awuo* (Dinka). It is served with groundnut sauce (*mulaa keimot*) and mixed with fish stew.

Sour *ugali* is popular among peoples of southern Sudan. It is made from fermented maize or sorghum flour (*akilamuat* or *kun ayupwach*) or sour milk in water (*akileben* or *kuncha*) or tamarind water (*asidamot/akilamot kunchuei*). *Ugali* is occasionally eaten with ghee (*zet*, *miok*) instead of milk. This is popular in southern Sudan (where it is called *kundiung*) and among pastoralists. It is common to find the Wambulu of Tanzania eating this dish (*faa*) as they sit on mats.

**Porridge (gruel).** Porridge (*uji* in Swahili) is a popular breakfast food in East Africa. It is a healthy food, especially for children and breast-feeding mothers, as it is easy to digest and provides both water and energy in readiness for the day. However, tea has replaced porridge as a breakfast food in most parts of East Africa, which has further complicated the problem of malnutrition.

Porridge is mainly made from cereals. Depending on the area, porridge may be thin or thick and may be flavored with sugar, salt, lemon, tamarind, baobab, coconut, cow ghee/butter, or milk. Probably the most delicious type of porridge is the fermented type, *obusera obupuute* (Kisa). Preparation of this dish, however, is tedious and time-consuming. In some areas this dish has cultural significance: Among the Kikuyu of central Kenya, a circumcised boy stayed in seclusion for a certain period, after which a caretaker (*mutiili*) led him to his mother's house, where the boy was served fermented porridge (*ucuru wa mukio*) as a sign of welcome. Finger millet (*wimbi*) porridge is the most popular of all porridges in East Africa.

**Rice (wali).** Rice is an important dish for the Ethiopian, Asian, and Muslim communities in East Africa. A common dish is *wali usambara*, which is rice prepared with coconut milk, salt, and a bit of oil. *Biriani* is a very spicy dish composed of rice (usually spiced) and spiced meat or chicken stews. *Pilau* is a spicy mixture of meat stew and rice that is popular both inland and in coastal areas. Spices in this dish include coriander, cardamom, cumin, pepper, cinnamon, cloves, onion, and garlic. *Pilau* is a popular dish in ceremonies all over the region. Preparing pilau is a delicate undertaking that requires a lot of patience and is usually performed by several women working together. *Pilau* is often eaten with spiced stews. *Wali ubwabwa* is a soft type of rice that cooks as one stirs it. *Mkate wa sinia* is made from rice flour mixed with yeast, water, sugar, and coconut milk and heated from below and above. All of these dishes are common in coastal areas.

**Wheat products.** Some amount of wheat is grown in the dryer highlands of East Africa, especially in Ethiopia and Kenya. Probably the most popular wheat food in the region is the Asian flat, round, thin bread widely known as *chapati*. Chapati is mainly served with stews, hot beverages, and soft drinks. In general, bread (*mkate* in Swahili, *dabo* in Amharic) has gained increasing importance in East Africa and now is the most popular starchy food for breakfast in urban areas.

The greatest variety of wheat products is found in Ethiopia. These include *kichab*, a dish made from a mixture of onions fried in oil and wheat flour. Another wheat product is *chechebsa*, which is cooked with *teff* (a type of cereal grass). Small pieces of salted dough (*lite*) are cooked on a pan without oil to a brown bread. This is buttered and spiced with pepper. *Fettira* is a thin breakfast bread made from wheat and egg and eaten with butter or yogurt.

*Arakip* (Arabic) or *ayup* (Dinka) is a type of dry bread prepared from maize, sorghum, wheat, or millet flour in Sudan. This bread is popular with people looking after cattle. *Kisira* (*kun pioth* in Dinka) is a Sudanese pancake like *enjera* that is prepared from maize or sorghum flour mixed with a little wheat and water. This pancake is served with beans, okra, or okra mixed with meat or *ayak* (*Corchorus*), a mucilaginous vegetable.

A whole range of wheat products, generally of European or Asian origin, are available in East African restaurants and homes. Common products include samosas (*sambusa*, *isambusa*), *kaimati*, *mandazi* and the related *mahamri*, and French bread, to name a few. *Mandazi* (*imandazi*, *ibitumbula* in Burundi), as they are called in Kiswahili, and the related *mahamri* are very popular types of buns served in restaurants. *Mandazi* are made by mixing dough with baking powder and sugar, while in *mahamri* the dough is mixed with yeast and often coconut milk. Both are cooked briefly in oil. In Dar es Salaam it is customary to eat *mandazi* with cooked beans (*mabarage*). The mixture is called *zege*, and it is eaten along with tea for breakfast. *Kaimati*, on the other hand, is spherical and more solid than *mahamri*.

Cakes are most popular in formal ceremonies, especially weddings. Among the Luhya, a popular cake is made by mixing ripe banana and maize flour, which is then kneaded into a dough, cut into balls, and wrapped in banana leaves and steamed in water. This sweet traditional cake (*omukati kwe lisotsi*) is served with tea or porridge.

**Barley.** *Cheko* (Ethiopia) is a type of spiced bread made from barley. Barley is also used to make a type of porridge known as *baso*. This is often flavored with honey, sugar, salt, and butter.

**Teff.** Teff (*Eragrostis tef*), a type of cereal grass, is grown traditionally only in Ethiopia, particularly in the western region. Most teff is made into *enjera* (*injera*), a huge, flat, flabby, rather elastic, and slightly sour pancake that is eaten with spicy meat or vegetable stews such as *doro watt* (hot, spiced chicken curry), *sega watt* (lamb sauce), and *key watt* (hot, spiced beef sauce). One tears off pieces of the pancake and uses them to scoop or roll the stews. *Enjera* is a typical food in Ethiopian restaurants all over the region. The Somali type of *enjera* (*canjeero*) is usually made from a mixture of maize and wheat and is often flavored with garlic and *iliki*. Sugar and milk cream are usually added to breakfast *enjera*. *Enjera* may also be made from a mixture of rice and wheat.

**Cassava.** Cassava is important at the coastal areas and among the Iteso and Luo of Lake Victoria basin and their relatives in Uganda, the Acholi, Langi, and Alur. Dry cassava can be roasted or boiled or eaten fresh. In the coastal region, fried cassava is flavored with lemon and powdered pepper and eaten with tea. Cassava is also deep-fried (*mgazija wa kukalanga* in Giriama). Cassava leaves (*mchicha kisamvu*) are used as a vegetable throughout the region.

**Potato (English/Irish potato).** Potatoes are used to make a popular stew (called *karanga* in Kenya) of carrots, tomatoes, meat, and onions. These are usually served with *ugali*, *chapati*, or *wali* (rice). Chips, or french fries, are the most popular foods in fast-food kiosks and are usually served with pork or beef sausages. In Burundi,

chips are also prepared from green bananas (*ibitoke*) and sweet potatoes (*ibijumbu*).

**Tannia and cocoyams or taro.** Tannia (*Xanthosoma sagittifolium*, called *Marumi* in the Meru region of Tanzania) is commonly used in Uganda and parts of Tanzania, especially among the Chagga, Ameru, and Arusha peoples. The tubers may be cooked with meat, beans, and maize or boiled and eaten with tea.

Cocoyams or taro (*Colacasia esculenta*), on the other hand, are widespread in the region and are commonly planted along water courses. The tubers are prepared in the same manner as tannia. Both tannia and cocoyams are popular breakfast foods.

**Yams.** In East Africa yams (*Dioscorea*) come in various types and include such varieties as the aerial yam or air potato, whose tubers are borne on the stems. Yams are prepared in the same ways as tannia and cocoyams.

**Bananas and plantains.** Many varieties of bananas exist in East Africa. Different varieties are used for brewing beer and cooking, and others are eaten when ripe, such as *kisukari* (Swahili) or *igisukari* (Burundi). *Kisimiti* and *kibungara* (found in the Mount Meru section of Tanzania) are varieties used to make traditional beers called banana and *mbege*. Also in Mount Meru, the soft varieties of bananas called Uganda and *ng'ombe* are preferred for meat and maize dishes. A cooked mixture of *ndizi ng'ombe* and maize meal, served with milk, is known as *losboro* and is a favorite food for the Arusha. In Tanzania, mashed beans and bananas (*kishumba*) are often served as a wedding cake with *dengelwa* (local sugar cane beer).

Green bananas (*matooke*) are the most important foods of the Baganda of Uganda. They are usually wrapped in banana leaves, steamed, and then mashed and eaten with a variety of steamed sauces usually containing groundnuts.

**Ensete.** Ensete (*enset*) is a bananalike plant (*Ensete edule*) exploited in southern Ethiopia for its pseudo-stem and leaf midribs—a source of a starchy product that is the staple food of parts of Ethiopia. This starch is fermented in the ground for periods lasting weeks or months. It is made into several products, including *kocho* (bread) and *bula* (porridge). *Kocho* is usually eaten with *kittifo* (*kitfo*)—hand-minced beef mixed with butter and pepper and served raw or cooked. A major disadvantage of ensete is its low protein content.

**Beans (kidney bean, common bean) and peas.** In Rwanda and Burundi beans are eaten for breakfast, lunch, supper, and as a snack. They are cooked with starchy foods such as sweet potatoes, green bananas, cocoyams, and cassava, as well as leafy green and fruit vegetables. In coastal parts of Tanzania, beans (*mabarage*) are cooked in coconut milk (*tui*) and served with *ugali*. Among the Giriama of Kenya this stew is known as *borobowa ya mabaragwe*.

Other pulses commonly made into stews are cowpeas and green grams, locally known as *pojo* or *ndengu*. Pojo stew (*borobowa ya pojo*) goes well with chapati, but it is also eaten with ugali and rice. In Ethiopia meat is prohibited during fast days. In such times, chickpeas, lentils, field peas, peanuts, and other pulses are used to make the local sauces and stews, *watt*, and *alechi*.

**Bambarra groundnuts.** Bambara (*Vigna subterranea*) seeds are boiled with maize (usually after overnight soaking) to make a type of githeri (*amenjera ke tsimbande* in Luhya) usually eaten as a snack. These seeds are also fried like groundnuts.

**Groundnuts and other nuts.** Groundnuts (*ibiyoba* in Burundi) are the most widely grown nuts in the region and are eaten raw, roasted, boiled, or in stews. In southern Sudan, raw roasted groundnuts are mixed with honey and eaten.

Groundnuts are extremely important in Uganda as they are used to make the most commonly used sauce—groundnut sauce—that is used to eat most starch foods. The sauce is usually mixed with meat, mushrooms, fish, chicken, or just tomatoes.

Among the Somali, a mixture of *iliki*, roasted groundnuts, and sugar is fried in ghee (*subag*) to make a sticky jellylike substance called *xalwa*, which is usually served with coffee or as a dessert after meals. Cashew nuts are grown in coastal areas and are a popular snack.

Gild (*Cordeauxia edulis*) is an evergreen shrub in the bean family that produces seeds called *yeheb* (*yibib*), which are eaten like nuts. These are very popular with Somali pastoralists. The inner part of marula fruit seeds (*Sclerocarya birrea*) is eaten fresh or roasted.

**Fish.** The most popular type of fish (*samaki*, *rech*) in East Africa is the tilapia (mainly *Oreochromis niloticus*) or *ngege*. People along the shores of Lake Victoria often enjoy this dish with ugali. The large Nile perch (*Lates niloticus*) is not as popular as tilapia, but it provides large quantities of meat, which are usually made into fish balls. Another common fish is the small sardinelike fish (*Rastrineobola argentea*) known by the names *omena* (Luo) and *dagaa* (Swahili). These cheap sources of protein are dried and sold in tins in most urban markets.

**Meat.** Meat (*nyama*, *ring*) is used to prepare a variety of sauces and stews (*mchuzi* in Swahili and *watt* in Amharic). In Ethiopia, *quanta* is meat that is cut in long pieces, smeared with powdered pepper, salted, and dried by hanging it above the fireplace for five to seven days. This meat is used to make a hot stew, *quanta watt*, which is served with enjera or mixed with broken pieces of enjera and eaten as *quanta firfir* (Amharic) or *sukume* (Oromic). Among the Luo of Kenya, such dried meat is known as *aliya* and is made into a stew that is eaten with ugali. Among the Somali, dried meat (*otkac* or *nyirnyir*) is usually prepared from camel meat (*bilib gel*). Strips of sun-dried meat are cut into small pieces that are fried

(usually in oil with garlic and *iliki*) and immersed in camel ghee (*subag*). Nyirnyir can last for several months and is usually served with tea, honey, chapati, and enjera. During breakfast, nyirnyir is served only to men. Preserved camel's meat and dates are served during Somali weddings. The date pulp is separated from the seed, mashed, and put around the preserved meat. On the wedding day, the meat basket is covered with a white cloth as a sign of purity or virginity. The dates and meat are served by the bride's mother to her new in-laws.

In Sudan, most of the meat from a slaughtered animal is dried (*shermout*). The layer of fat around the stomach is also dried and is called *miriss*. Internal organs may also be dried, pounded, mixed with some potash, and molded into a ball that is allowed to dry slowly to make *twini-digla*. The large intestine may also be cleaned and stuffed with fat and hung to dry as a type of sausage.

A common way of serving meat is to pile pieces of meat and sweet pepper on a stick and roast them. This type of meat, known as *mshikaki* (*mshakiki*, *umushikaki* in Burundi), is very common in the streets of coastal towns in the evening.

**Chicken.** Most households in East Africa raise chickens, which are usually prepared for guests. The various parts of the chicken hold significance in different regions. In western Kenya, for example, the tail part of the chicken is reserved for the male head of a family. Among the Kamba of Kenya, a gizzard is served to the most important person in a group of visitors, while among the Luhya the gizzard (*imondo*) is never shared. If two people did share it, it is believed they would always be in disagreement.

**Milk and milk products.** The nomadic tribes of Sudan make a type of cheese called *kush-kush* eaten with sorghum porridge. Camel herders put milk into a skin bag that is fastened to the saddle of a camel, and the milk (*gariss*) is allowed to ferment. This is a major source of food for the herders as they roam with their animals in remote areas.

In the twentieth century many dairy products entered the Sudan from the North, including *jibnabeida* (white cheese), *zabadi* (yogurt), and black cumin-flavored *mish* (Dirar, Harper, and Collins, p. 20).

**Meat substitutes.** In rural western Sudan, a popular substitute for the meat flavor is *kawal*, a strong-smelling product derived from a two-week long fermentation of the pounded green leaves of the wild legume *Cassia obtusifolia*. In the same region, the oil seedcake remaining after oil extraction from sesame seed (*Sesamum orientale*) is fermented for a week to make *sigda*, another meat substitute. Sigda is usually consumed in a vegetable stew. *Furundu*, a similar meat substitute, is prepared from the seeds of *karkade* or red sorrel (*Hibiscus sabdariffa*). All these products are dried after fermentation in the form of hard, irregular, small balls and may keep for a year or so.

**Leafy vegetables.** Many leafy vegetables are used as an accompaniment for starchy foods such as ugali. These vegetables are prepared in a variety of ways—in many cases as a mixture. Common traditional leafy vegetables include baobab, cowpea, amaranth, vine spinach (*Basella alba*), Ethiopian kale (*Brassica carinata*), spiderplant (*Cleome gynandra*), jute (*Corchorus olitorius*), crotalaria, sweet potato, water spinach (*Ipomoea aquatica*), African nightshades (*Solanum* species), hibiscus (*Hibiscus sabdariffa*), *Oxygonum sinuatum*, African eggplants (*Solanum* species), pumpkin, cocoyam, bean, and cassava. Ethiopian kale (*gommen*) is important during fast days in Ethiopia when meat is prohibited. It is used to make local sauces, alecha. A few nontraditional leafy vegetables like cabbage have gained importance in the last few decades. Kale (*Sukuma wiki*), introduced in the twentieth century, is now the most highly consumed vegetable in urban parts of Kenya.

**Fruit.** A wide range of traditional and exotic fruits are consumed in East Africa, usually as snacks. Mango, citrus fruits, banana, jackfruit, papaya, melons, guava, passion fruit, custard apple, and avocado pear are all common market fruits. Many of the traditional fruits are picked in the wild, such as baobab (*Adansonia digitata*), wild custard apple, saba, carissa, dialium, flacourtia (Indian plum), marula, vangueria, tamarind, vitex, and jujube.

The dry cream-colored pulp of baobab, which is sour-to-sweet in taste, is eaten raw or may be dissolved in water and stirred to a milky state, at which time the seeds are sieved off and the juice is used as a sauce or for sour porridge. The pulp-coated seeds (*mabuyu*) are colored, sugar-coated, and sold as sweets in coastal towns (Swahili).

**Beverages.** In general, traditional East African cultures do not favor the use of juices. Juice made from ripe banana (*umutobe*) is commonly served in Rwanda, and a hot drink and juice made from *karkade* (*Hibiscus sabdariffa*) are common in Sudan, but these are exceptions. However, a great variety of alcoholic drinks are made in the region. *Muratina* is a common weak beer served in rural parts of Kenya. It is prepared from honey, sugar, or sugar cane and is named after the fermenting agent, the sausage tree fruit (*Kigelia africana*). The Maasai use aloe root (*osuguroi*) in place of sausage tree fruit for fermentation.

*Busaa* (Luhya) or *amarwa* (Baganda) is an alcoholic drink as well as a food. It is made mainly from sorghum, maize, or millet flour. In Rwanda, a similar type of drink—*ikigage*—is consumed as a drink and as food. Among the neighboring Bakinga of southwest Uganda, a similar drink called *omuramba* is made from sorghum. However, a more popular drink in Rwanda is *urwangwa*, which is made from ripe banana. It is popular in ceremonies and among men when discussing important issues.

In Ethiopia, *berize* (Amharic, Oromic) is prepared with honey and the boiled stems of a tree called *gesho* (*Rhamnus prinoides*). Berize is fermented to a weak,

A Kenyan woman is shown chopping mallow leaves to make a traditional stew that is eaten with fish and *ugali*. *Ugali* is stiff cornmeal dough pressed against the elbow to make a cup, which is then used as an edible scoop. PHOTO BY Y. MORIMOTO.

amber-colored wine called *tej* (*t'ej*). It is served in special long-necked bottles after meals in ceremonies. *Tella* (*talla*) is similar to Kenyan *busaa* but is prepared by fermenting roasted maize flour and barley.

*Mnazi* or *pombe ya mnazi* is palm wine. It is a popular drink in all coastal areas where coconut trees grow. *Chang'aa* is a popular but illegal spirit made by distilling fermented grain (such as maize) or banana. It has a variety of local names, such as *kumi kumi* in Nairobi and *waraj* in western Kenya and in Uganda. The Ethiopian version of it is *katikala* (in Amharic) or *areq* (Arabic) and is usually made from finger millet. *Chang'aa* has over the years been responsible for a number of deaths due to unscrupulous sellers who add illegal chemicals to the beverage to increase its potency.

Sorghum is used in Sudan to brew a large variety of opaque and clear beers using complex methods. Common examples are *merissaan* (opaque beer) and *assaliya* or *um-bilbila* (clear beer). Traditional wines include *sherbot*, *nebit*, and *dakkai* made from dates that are normally found in the northern dry parts of the country. In southern Sudan, *duma* (a type of wine) is made by fermenting diluted honey.

*Liralira* is a local spirit of the Acholi and Lango in Uganda. It is made from finger millet and cassava flour. The neighboring Sudanic communities of Lugbara and Madi have their own brew made from cassava, known locally as *ngoli*, while the Iteso of Kenya and Uganda have a version called *ajono* that is made from finger millet. Many other alcoholic drinks are found in East Africa and go by such names as *mbege* and *karubu*.

**Coffee.** Although Eastern Africa is one of the largest producers of coffee, the beverage is not very popular except in its original home—Ethiopia. Among the Muslim communities of the coastal region, very strong coffee (*kahawa chungu*) is served in small cups along the streets in the evenings and early in the morning.

In Ethiopia, raw coffee (*bun*) is roasted on a pan until it turns brown. It is then spiced and ground into flour on a stone. The coffee is served in an earthenware kettle (*jebena*). Coffee-drinking is an important occasion in many communities in Ethiopia, Sudan, and Somalia. Among the Somali, coffee is served in small cups with date fruits or *xakwa*.

**Tea.** Tea has replaced porridge as the morning drink in many homes in East Africa. In many rural restaurants it is customary to serve tea as soon as one sits down. The common way of preparing tea in homes and in most restaurants is by boiling water and adding tea leaves and milk, all mixed together (*chai ya maziwa*). Tea without milk is popularly known as *strungi* (from “strong tea”) and as *shaah biiges* in Somali. The Maragoli and Taita of Kenya value tea highly.

**Stimulants.** *Khat* (also known as Abyssinia tea or *miraa*) is a popular stimulant in East Africa. The bark from fresh young shoots is peeled off and chewed. *Khat* is an important plant during wedding ceremonies among the Somali and Boran of Kenya and Ethiopia.

**Spices/flavorings.** Probably the most widespread item used for flavor is salt. In many traditional societies, salt is a filtrate of ashes from dry bean leaves, banana peels, water reeds, sorghum head, and normal ash. Most communities used samli or ghee to flavor food. In Tanzania and most coastal parts of the region, coconut milk is also used to flavor food. Grated coconut and water are squeezed in a woven bag to produce concentrated milk.

Tea and a few other beverages are flavored with a number of things, the common being ginger (*tangawizi*) and *masala* (a mixture of spices but usually containing coriander). Tea can also be flavored with lemon grass (*Cymbopogon citratus*), lemon (*Citrus limon*), and *mjafari* (*Zanthoxylum chalybeum*). The art of flavoring is most established in Ethiopia and among the Asian community in the region. The sauces are therefore extremely hot. In Ethiopia, the powdered spice *berbere* (also *berberi* or *awaze*) has hot pepper as the main ingredient but may contain a dozen other spices. Curry powder (*bizari*), another mixture of spices (usually cardamom, turmeric,

ginger, cinnamon, and chilies) is more popular in the rest of the region. Spicing, however, seems to be more of a culture in Ethiopia and coastal regions where there has been long Islamic and Asian influence. A variety of spices are used, the more common ones being black pepper, *piper nigrum* (*pilipili manga*); cardamom, *Elettaria cardamomum* (*iliki*); chili pepper, *Capsicum annuum* (*pilipili kali*); cinnamon, *Cinnamomum verum* and *C. aromaticum* (*mdalasini*); cloves, *Syzygium aromaticum* (*karafuu*); coriander, *Coriandrum sativum* (*giligilani*); cumin, *Cuminum cyminum* (*bizari* or *nyembamba*); curry powder (*bizari*), a mixture of different spices; garlic, *Allium sativum* (*kitunguu sumu* or *kitunguu saumu*); ginger, *Zingiber officinale* (*tangawizi*); nutmeg (*kungumanga*) and mace, *Myristica fragrans* (*kungu*); sweet pepper, *Capsicum annuum* (*pilipili hobo*, *pilipili mboga*); tamarind, *Tamarindus indica* (*ukwaju*); and turmeric, *Curcuma longa* (*manjano*). Many of these are grown locally and for some, like cloves in Zanzibar Island, production is of world significance.

#### NORTH AFRICA

A Moroccan proverb says: *Mâ kainsb el-kalâm cala et-tacâm*, “Where there is food, there is no talking.” Indeed, as a sign of respect for the food that God has provided and the host or hostess has served, North Africans consider it impolite to converse while eating. The food itself, however, does not remain silent. Food talks. Meals convey messages. Perhaps more than anything else in North African cultural praxis, food habits constitute a rich language through which the region’s history is told, social distinctions are expressed, religious feasts are celebrated, and seasonal changes and transformations in the life cycle are marked.

#### Historical Influences

The history of North Africa comes to the fore in both particular ingredients and dishes that are shared by most Maghrebi as well as in regional differentiation between specific dishes and ingredients. Influences from the Roman presence (200 B.C.E.–300 C.E.) can, for instance, be recognized throughout the region as wheat is the basis for the two main staple foods, bread and couscous, a steamed grain of crushed wheat or coarse flour. Is-

lamization in the seventh century can, of course, be recognized in the prohibition of pork or wine, although flourishing vineyards can be found throughout North Africa. Arab influences that accompanied early Islamization, such as the consumption of rice, native east African vegetables such okra and *mlùkbîa* Jew's mellow (*Corchorus olitorius*) and the use of *fliyu* and mint in meat and vegetable dishes, are more pronounced in east Algeria and Tunisia than in regions further removed from the Levant, such as western Algeria and Morocco. All three countries have adopted the Arab preservation technique of drying meat, called *gedîd*, in which salt and spices are rubbed into the meat, which is then left to dry in the sun.

Morocco is the only North African country that was not occupied by the Ottoman Empire during its presence in the region (1500s–1700s). Correspondingly, dolmas, stuffed vine leaves, like Turkish and Syrian puff pastries such as baklava and *brîk*, are commonly prepared in formerly Ottoman Algeria and Tunisia, but do not feature in Moroccan cuisine. On the other hand, Algerian, Tunisian and Moroccan cookery alike have been heavily influenced by the introduction of crops from the New World such as tomatoes, courgettes, sweet peppers and potatoes. These foods were introduced to North Africa before they were introduced to central Europe. Potatoes, however, never became as popular in North Africa as they would become in Europe.

Food habits in all three North African countries discussed here have been influenced by French occupation. In Algeria, the French occupation lasted the longest (1830 to 1962). Not in the least because of the influx of a large number of French settlers, all spheres of life were influenced by it, including Algerian cuisine. Tunisia was occupied in 1881 and largely shared the same fate, at least in the cities. By the time Morocco became a French protectorate in 1912, the French occupational policy had changed. Fewer settlers were moved in, and more attention was paid to the preservation of “traditional culture.” In terms of food habits, these different policies can be recognized in Morocco’s being the only Magrebian country where most people still eat homemade round breads rather than bakery bought baguettes. Most city dwellers in Morocco, however, like those in Algeria and Tunisia, nowadays drink café-au-lait for breakfast. Indeed, examination of the three daily meals that are consumed throughout the Maghreb—the *ftûr* or breakfast, the *ghrdâ*’ or midday meal, and the *cashâ*’ or evening meal—brings to light more variations between rural and urban areas than between countries. The distinction between rural and urban food habits corresponds, albeit not exclusively, with the distinction between the poor and those who fare better economically. On the whole, for example, less meat is consumed in the countryside than in the cities, and the same is true for milk and butter. Also, in the cities, fast food chains are becoming increasingly popular and when guests come for dinner, there are always a few bottles of cola and other carbonated soft drinks on the table.

## Daily Meals

In the cities breakfast usually consists of a café-au-lait with bread and butter or jam, sometimes with *La Vache Qui Rit*, wedges of processed cheese that seem to have conquered much of the developing world. The Moroccan city of Fès is famous for its *barsba*, an unleavened very thick and crusty flatbread made of crushed wheat and *arachide* or olive oil, preferably eaten with fresh cheese. Because the flatbread remains tasty for a long time, it is popular with travelers. Because it is filling, peasants are also fond of it. If leavened bread is eaten for breakfast in rural areas, it is more likely to be served with olive oil than with butter, and it is eaten with tea more often than with coffee. Heavy agricultural work demands a substantial meal, however, so that *assîda* or *bsissa*, water-based porridges of semolina or grilled barley flour, are more common rural breakfasts. Yesterday’s leftovers of couscous or soup may, of course, do just as well.

**Lunch.** Lunch consists of a hot meal, which in Morocco is the most important meal of the day, while in Algeria and Tunisia the dishes that are served for lunch or dinner are interchangeable. Among the urban elite, especially in Algerian towns, lunch may consist of dishes from the French cuisine, such as fried meat, french fries, and salads. In Morocco and Tunisia, most people prefer to eat either a *tajîne* (tagine), a stew, also called *marqa*, or a couscous. *Marqas* tend to be more popular than couscous, especially in urban areas. Nowadays, *marqas* are almost invariably prepared in pressure cookers, but most people agree that they taste much better when prepared in a *tajîne*, the traditional cone-shaped earthenware pots that gave this kind of dish its name.

The sauce that forms the basis of a *marqa* or *tajîne* varies per region. In Morocco, saffron is traditionally used to color the basic sauce yellow. Nowadays, saffron is nearly always replaced by artificial yellow coloring powder, which is much cheaper but lacks taste. To make a *marqa*, chopped onions and garlic cloves are fried in *arachide* oil into which the (artificial) saffron is stirred. Next, fresh chopped coriander and parsley are added, then salt or “knurr,” that is, stock tablets (the brand name has become the generic name) together with spices such as black pepper, paprika, cumin, and sometimes ginger and/or cinnamon. A famous mixed spice is *râs el-bânut*, “the master of the shop,” which should consist of twenty spices, among which powdered rose buds and lavender, and, as tourists are meant to believe, the aphrodisiac “Spanish fly.” *Râs el-bânut* is classified as a “hot” spice. Consequently, it is almost exclusively used in winter. Other “hot” spices such as black pepper, ginger, and paprika, are also used more liberally in winter than in summer, when mild spices like cumin and cinnamon are used more. After spices have been added, peeled and chopped tomatoes are put in, together with meat. Last of all, water is added, after which the sauce is left to simmer until the meat is tender.

Only very little water is added to the *tajîne*. The earthenware pot is placed on a charcoal burner, and it takes hours for the meat and vegetables to cook in their own juices. In Tunisia, tomatoes and *harissa*, a chili paste, form the basis for the sauce so that the marqa is red rather than yellow. Otherwise, much the same spices are used, although cumin may be replaced with caraway. In Algeria, in regions closer to Morocco, the basic sauce is yellow, while in regions closer to Tunisia it tends to be red. Marqas are eaten with bread. In most Moroccan families, the housewife or one of her servants prepares the dough for the bread, which is then brought to the *ferrân*, the public oven, where it is preferably baked shortly before lunch, so that the bread is still slightly warm when lunch is served. Tunisian and Algerian women often reheat the bakery-bought bread before serving it.

Bread and couscous are never eaten together. While in urban areas *marqas* are prepared more often than couscous, in rural areas it is the other way around. Unlike other dishes that are associated with the countryside, however, a good couscous is considered a festive meal by urban and rural dwellers alike. Most Maghrebi eat it for Friday lunch, Friday being the most blessed day of the week. It is also a favorite dish for weddings and other big dinner parties, not in the least because it is easy to prepare in great quantities. A Friday or party couscous tends to contain more meat and a larger variety of vegetables than those eaten during the other days of the week. Meat is quite expensive in North Africa, and especially in the countryside, both daily *marqas* and different kinds of

couscous consist largely of vegetables and pulses such as chickpeas, lentils, and white beans. In coastal areas, fish, mostly deep fried, is also included.

In general, pulse-based dishes are associated with poverty. *Bisâra*, for instance, a very thick sauce of cooked dried and peeled broad beans to which lots of garlic, olive oil and cumin is added, is a much loved dish, especially in winter. Yet one would not dream of serving it to guests. The same goes for *usbân*, a Tunisian couscous with offal, the cheapest “meat” there is. Instead of these cheap—albeit delicious—meals, guests should be served dishes that consist mostly of meat, such as the originally Ottoman *l-hamm el-blâ*, cinnamon- and ginger-spiced veal, served with prunes and fried almonds, or *dajâj zâtûn*, chicken with green olives, salt lemon preserve, hard-boiled eggs, and, again, fried almonds. Throughout the Maghreb, *bstila*, originally from Fès, has also become a favorite dish to serve guests. It is savory pie made of flaky pastry filled with pigeon or chicken that is sprinkled with cinnamon and powdered sugar before serving. The latter ingredients are also used to top off sweet couscous that are served for dessert.

**Tea and evening meal.** As was mentioned before, in Algeria and Tunisia the dishes that are served for lunch or dinner are interchangeable. These meals are eaten around six or seven o’clock. In Morocco, the *cashâ* tends to be eaten somewhere between eight and nine o’clock. This allows women to visit each other in the afternoon and have tea together, which is followed by coffee just

before they go home. The green tea that is flavored with fresh mint and much sugar and may be served with *el-ghbraif*, flaky pastries fried in a pan and served with honey or castor sugar, or with *beghrîr*, leavened pancakes served with honey, butter or olive oil, or *sfinj*, fritters. Although men also occasionally eat sweet pastries, throughout the Maghreb they are typically associated with women.

Because the evening meal is served rather late in Morocco, women who stay at home have tea with bread or *barsba* before they prepare dinner. Except when there are guests, dinner in Moroccan cities is light, consisting of soup, small meatballs in a tomato sauce, or milk-based porridges of rice, semolina, or pasta. In rural areas where those who work on the land have not been able to come home for lunch, dinner is the main meal and more substantial.

### Meals for Special Occasions: Ramadan

During the month called Ramadan, between dawn and sunset, Muslims refrain from eating, drinking, and sexual contacts. After sunset, all this is allowed again. Ramadan is as much a month of feasting as of fasting. Indeed, many people gain weight during the fasting month. Some people save money for months in order to eat meat and luxury foods during the Ramadan nights. Much like Christmas meals in Western countries, Ramadan meals are family dinners. More often than not, friends or neighbors are invited to join in as well. Some only pop in for the sunset meal, others stay until the last meal that is served an hour before dawn. Sharing extends to strangers: every day towards sunset, people bring soup and couscous to the mosque for the poor and homeless.

**Ramadan breakfast.** Like most Muslims in the world, North Africans follow the example of the Prophet Mohammed (570–632), who used to break the fast by eating a date and drinking a sip of water or milk. They then perform the sunset prayers, after which the *ftûr* is served. In Morocco, *harîra*, nutritious tomato soup with meat, chickpeas and lentils, has become the national dish for breaking the fast. Besides *harîra*, what should also always be present on the breakfast table are *shebbakiyyât*, also known as *grioush*, deep-fried pastries with anise and cinnamon, which are dipped in honey or caramel when still hot and are then sprinkled with sesame seeds. *Beghrîr*, pancakes, are another favorite, as are hard-boiled eggs and olives. After having eaten two or three bowls of *harîra*, coffee with much more milk than usual is drunk.

Algerians and Tunisians also have soup for a Ramadan breakfast, but do not share the Moroccan habit of eating sweet pastries with soup. They prefer to eat large quantities of cakes and sweets with the coffee that is served later in the evening. To digest breakfast, many North African city dwellers go out to attend the open air performances and other special Ramadan festivities that are organized in town, buying orange juice, buttermilk, roasted sunflower seeds, peanuts, or chickpeas from street vendors as they stroll along.

**Ramadan evening meals.** Tunisians and Algerians combine the Ramadan breakfast and the evening meal. They eat a date and a bowl of soup before performing the evening prayers, after which they return for the evening meal, which in all three countries should always contain a fair amount of meat during Ramadan. *L-hamm el-blû* (sweet veal with prunes) is a favorite Ramadan dish in Algeria, while in Tunisia *keftajî*, a stew with meatballs or a well-filled *marqa* (stew) may be served. Tunisians may also eat parched fish for a Ramadan dinner. This is frowned upon by Algerians and Moroccans: fish is easily digestible and leaves you thirsty, two qualities that are not very helpful during the fast. Ramadan dinners are served with more side dishes (eggs, olives, salads) than during other months of the year, and a larger variety of fruits appear on the table for dessert.

A typically Moroccan tradition occurs on the fifteenth night of Ramadan. That night, every family wants to eat a home-slaughtered chicken or rabbit, which gives this special dinner a connotation of a sacrificial meal. No similar tradition exists in either Algeria or Tunisia. What all three countries do share is the tradition on the twenty-seventh of Ramadan to visit the graveyard, clean the graves of relatives and have prayers said for them. On the way to and from the graveyard, children in the street and poor people who have gathered at the gates of the graveyards are given *sadaqa*, alms consisting of dates, figs and sweet bread.

**Meals at night during Ramadan.** People who have guests stay awake until the *shûr*, the last meal before dawn, in the meantime enjoying lots of coffee and pastries such as baklava, *brik* (sweet puff pastries) and *sefûf*, ground and grilled sugared cereals and nuts. In the old quarters of towns, those who go to sleep are awakened for the *shûr* by musicians going through the streets. Most people have a light *shûr*: French toast, a milk-based *assîda* (porridge), or a *mesfûf*, (sweet couscous). In rural areas, however, the *shûr* may consist of a more substantial meal.

**The feast meal.** The last few days of Ramadan, women are very busy preparing cookies, cakes and pastries for the *cîd es-saghrîr*, the feast that ends the fasting month. In rural areas, nearly every one makes *kacak*, hard biscuit rings with anise and fennel seeds. In general, townswomen make a greater variety of cakes, cookies and pastries. In Algeria, women in Constantine are the most famous cookie makers, to be followed by those of Algiers and Blida. These cities used to have large Jewish communities, and Muslim women are said to have learned the art of cookie baking from Jewish women. Particularly popular for the concluding feast of Ramadan are *maqrûd*, date- or almond-filled fried cookies made from semolina, and *qnîdelet*, marzipan cigars. In Morocco, Fès is famous for its good pastries, such as the *kacab el-ghrazâl*, “gazelle horns,” horn-shaped pies filled with almond paste.

In Morocco, many people find it important that the first meal that is eaten on the feast that ends Ramadan should be a white porridge. The color white symbolizes

the purity that one has attained by fasting a whole month. The rest of the day is spent paying visits and receiving guests. In every house that they visit, people are served coffee or tea with lots of cookies and pastries. Not surprisingly, many people do not eat dinner on the first day of the feast concluding the fasting month.

### The Feast of Immolation

On the tenth day of the *hajj*, the pilgrimage to Mecca two months after Ramadan, all pilgrims sacrifice a ram to commemorate how Ibrāhīm (Abraham) slaughtered a ram as a last-minute substitute for the son he was willing to sacrifice as an act of obedience towards God. It is recommended by Islamic law that those Muslims elsewhere in the world who can afford it also sacrifice a ram. Voluntary fasting is recommended the day before the ritual sacrifice. Some people fast until the first meat of the sacrificed ram is served later in the day. Only men are allowed to slaughter. Female household heads call in a butcher. After the slaughtering, the rest of the day women are busy processing the meat.

Much local symbolism is attached to the various parts of the sacrificial ram. Mothers, for example, dip a finger in the blood that flows from the cut throat to mark the forehead of their children so as to ward off the evil eye. The sheepskin not only makes a perfect prayer mat, but is also thought to relieve the pain of a woman in labor who lies down on it. Of particular importance is the liver, the organ that is considered the seat of compassion. Barbecued liver is the first meat that is consumed on the day of the sacrifice. Women see to it carefully that there is a skewer for every member of the family. When someone does not make it on time for the barbecue, his or her skewer will be kept apart for them. Sharing the liver with all family members expresses and fortifies the family bond. The pieces of liver on the skewers given to girls are wrapped in the fat tissue that covered the heart of the ram, as this is believed to enhance finding a husband with a good heart.

Nowadays, pieces of meat that are not distributed among the poor can be stored in refrigerators and freezers, but the tradition of making *gedîd*, dried meat, has not disappeared. Slices of meat are put in a spicy marinade overnight. The next day, pieces of paunch are filled with the marinated chunks and then tied into bundles that are left to dry in the sun for several days. When a woman has difficulty getting pregnant, her friends may organize a lunch party for her by collecting two balls of *gedîd* from each woman who will attend, which are then served in a couscous. The chances that the honorary guest gets pregnant are thought to have improved after this ritual lunch. A tradition in Marrakesh (Morocco) is to dry the tail of the ram to save it until the *Ashûra*, the celebration of the New Year.

### The *Ashûra* or Islamic New Year

Exactly one month after the Feast of Immolation, the *Ashûra* is celebrated on the tenth day of Muharram, the

first month of the Islamic year. Traditionally this is the day on which the religious duty of performing *zakât*, the legal almsgiving, is performed. *Ashûra* concludes a transitional period of ten days between the old and new year. During this period, some people observe fasting. In Marrakesh, the fast is concluded by having a couscous with the preserved tail of the sacrificial ram, which thus comes to symbolize the farewell to the past year. In Tunisia, on the ninth day of Muharram people tend to eat chicken with very thin noodles, while on the tenth they prepare a couscous or *marqa* with mutton. In Algeria, dinner on the tenth of Muharram should be sweet, and often contains raisins, prunes and cinnamon. In Morocco, *Ashûra* is not linked to any special meal, but what is shared with the other countries is that women prepare or buy *krishlât* or *fakîya*, mix of raisins, figs, nuts, and dime-sized cookies. *Krishlât* is eaten at home and distributed among children in the neighborhood.

Despite the influence of the former French occupation, New Year celebrations according to the Christian calendar do not, as yet, receive much attention. An exception must be made for Tunisia, where people eat *mlûkbîa* or other dishes from spinach-like plants on New Year's Eve. Green is the color that symbolizes Islam. The green color of the New Year's Eve dish also symbolizes the hope for a "green," that is, prosperous, year.

### The *Mûlûd* or Birthday of the Prophet

On the twelfth day of the third month of the Islamic calendar, the *mûlûd* or birth of the Prophet Muhammad is commemorated. Every country has its own special dish on this occasion. In Tunisia and Morocco, most families have *assîda* for breakfast, a semolina porridge prepared with milk and sweetened with honey. Poorer people and those in the countryside keep it simple, while people in the cities and those who are better off may add raisins and orange blossom water to the porridge. In Algeria, people in the east are known for eating *sfînj*, fritters, for breakfast, while *qatawarmi*, chicken with turnip and chickpeas, is eaten for dinner across the country. In Morocco chicken or beef with prunes and almonds is a favorite dish on the Prophet's birthday.

### Life Cycle Rites

**Birth.** While in North African cuisine both hot and mild spices are used, the two should not be mixed. According to Tunisians, the combination of hot and sweet spices is thought to cause diarrhea, just as fish with milk is thought to cause skin diseases and tea with buttermilk stomach aches. In all three countries, dishes prepared for special occasions related to life cycle rites tend to be mild and sweet. Cinnamon, raisins, prunes, and nuts are recurring ingredients. On the occasion of a birth, for example, an Algerian new mother is offered semolina porridge with honey. In Morocco the mother is offered *sefûf*, ground and grilled cereals and nuts, flavored with sugar, anise, and fennel. *Sefûf* is considered to help her

regain her strength and to pass it on to her baby through her breast milk. According to a Moroccan tradition, when the baby is a girl, a cock should be slaughtered for the first meal that the mother eats after having given birth, the cock symbolizing the future husband of the girl. If the baby is a boy, a hen is slaughtered for this dish. On the seventh day after birth, the day on which the baby is given its name, different kinds of pancakes such as *ghbraif* and *beghrir* are prepared for breakfast. In families that can afford it, a sheep is sacrificed to thank God. It is prepared for the guests who attend the name-giving party.

**Marriage.** According to a Moroccan custom, the last meal that a mother of a Moroccan bride prepares before her daughter leaves her parental home to join her husband should be a dish that was “stirred with no spoon,” lest her husband should prove to be an easily agitated and restless man. Meanwhile, the guests at the groom’s house are offered chicken with lemon preserve, almonds and hard-boiled eggs, which symbolize fertility. In Algeria, guests are served *shtetba*, “the dancing (chicken),” a name referring both to the dancing of the guests and to the movements of the chicken in the pot as it simmers in its sauce of tomatoes, potatoes, garlic, and red pepper. Often, the parents of the groom slaughter a ram or calf on behalf of the bride to serve to the wedding guests. In all North African countries the bride and groom offer each other dates and milk before they withdraw to a room to consummate the marriage. Like eggs, dates and milk symbolize fertility. For Algerians, an additional explanation is that in this way, the partners eat each other’s “salt,” thus becoming part of each other. On the morning after the marriage ceremony, the parents of a Moroccan bride traditionally send the newlyweds a rice porridge and *bûzelûf*, a boiled head of sheep. The whiteness of the porridge symbolizes the purity of the bride while the head expresses the wish that she uses her head in running her household. On the seventh day after the wedding, the family of the bride comes to visit her and are offered fritters (*sfînj*) and porridge (*assîda*) sweetened with honey.

**Mourning.** In the house where someone has died, traditionally no fire should be lit to prepare food for three days. Those who come to express their condolences bring along food for the bereaved, usually a very simple couscous and hard-boiled eggs. Besides fertility, eggs also symbolize death and mourning, particularly egg shells, which break easily. On the fortieth day after the funeral, a ram is slaughtered and its meat prepared for those who gather to recite the Qur’an on behalf of the deceased. The same ceremony is repeated a year after the death.

### Jewish Food Habits

For a long time, there have been Jewish communities in North Africa. Some, such as the Algerian Bahusi have lived there since the destruction of the Temple in Jerusalem more than two thousand years ago. Others settled there after their expulsion from Spain after the Reconquista (1492). After independence in the 1960s, the

majority of Jews emigrated to Israel, but all North African countries continue to have Jewish minorities.

There are only a few respects in which food habits of North African Jews differ from those of Muslims in the region, and these all pertain to religious prescriptions. Kosher cooking requires that meat and dairy products should not be mixed and that different cooking utensils should be used for each. Like most Muslims, Jews use oil to fry their meat, but unlike Muslims, they will never add *smen*, salted clarified butter. Also, when Jewish women make bread, traditionally they always throw a small piece of the dough in the fire, symbolizing the setting apart of a portion of their meals for the poor.

Furthermore, special meals are associated with particular moments in the religious calendar. On occasion of the Hebrew New Year, for example, as is the case among Algerian Muslims on the tenth of Muharram, sugar replaces salt, and sweet dishes with raisins and prunes predominate. Moroccan Jews prepare a dish with seven vegetables and a sheep’s head, symbolizing merit and good fortune. During the days leading up to Yom Kippur, the fast on the tenth day of the new year, many families eat chicken, since for each family member a chicken should be sacrificed on occasion of the New Year to commemorate Abraham’s sacrifice. Women also prepare “Yom Kippur bread,” with almonds. To break the fast on the evening of Yom Kippur the table is set with cakes. The day after Yom Kippur, at midday Moroccan Jews eat chicken with olives, followed by *beraniya*, fried and sweetened eggplants sprinkled with sesame seeds and cinnamon.

Sukkoth, the Feast of Tabernacles, which begins five days after Yom Kippur, lasts seven days. On the first day, Jewish women in Morocco prepare a couscous. Throughout the week of the Sukkoth holiday, women serve better meals than usual. In Algeria, chicken is again a favorite, being followed by lots of fruit for dessert. On the occasion of Hanukkah, the festival of light, during which the rededication of the Temple in 165 B.C.E. is commemorated, women make their famous *qnîdelet*, marzipan cigars, and *magrûd*, date- or almond-filled fried semolina cookies, as well as the same kind of pancakes, fritters, and puff pastries that have been mentioned above for Islamic celebrations. Tu-Bishvat, the festival of trees, is celebrated by Moroccan Jews by eating fifteen different kinds of (dry) fruits. Purim, the feast commemorating the deliverance of the Jews by Esther from a massacre, is even more a feast of pastries, and kilos of them are exchanged between women and distributed among children and the poor.

For Pesach, when the Exodus from Egypt is commemorated, the ritual meal should at least consist of a salad with *marûr*, a bitter herb, referring to the bitter life under Egyptian rule; a glass of salt water, representing the tears and sweat shed; and eggs cooked hard in ashes, a symbol of the destruction of the Temple. In Algeria,

Jews eat a lamb's leg on this occasion. The lamb symbolizes the beginning of a new life, and its leg, God's "extended arm" with which the Egyptians were hit when the ten plagues fell upon them. The lamb's leg also commemorates the fact that each Jewish family in Egypt was asked to slaughter a lamb and smear its blood on the doorposts of their houses so that these could be identified as those that were to be saved. Last of all, matzos, biscuits representing unleavened bread that was eaten during the journey through the desert are eaten, as are fresh, green vegetables, also representing a new beginning. On the evening of Mimuna, the last night of the Passover festival, many people only eat milk products, but some families place fish on the table as a symbol of fertility.

Seven weeks after Pesach, Shevuoth is celebrated. According to some this was originally an agrarian festival, but later became linked to the commemoration of the covenant of Mount Sinai. On this occasion in Morocco, "Angel's Hair," a pasta sprinkled with cinnamon and surrounded by meat or chicken, is traditionally served.

On the Sabbath, all work must cease, and no fire should be lit. Therefore, women make enough bread on Fridays for two days and prepare the fish or chicken that will be eaten on the Sabbath. A special Sabbath dish in Morocco is *skhîna*, consisting of eggs, potatoes, rice, chickpeas and meat. Traditionally, *skhîna* was prepared in earthenware casseroles that were hermetically sealed and cooked overnight in the public oven or in the still glowing ashes of the fire used to heat the public bath. This way, it was still warm when eaten for lunch on Saturday. Nowadays, most women prepare *skhîna* at home.

The meals on the Sabbath tend to be better than on other days of the week, often consisting of the same dishes that Muslims eat on Fridays. The festive meals that are served on occasions that mark the life cycle also tend to be the same as those of Muslims, such as the "dancing chicken" for marriages. Indeed, North African Jewish and Muslim cuisines overlap widely, as do the meanings of foodstuffs and ingredients used. For both Jews and Muslims, salt is purifying, bread contains *baraka*, God's blessing, dates symbolize fertility, eggs both fertility and mourning, green vegetables represent the wish for a new year of abundance, and pulses are associated with poverty.

## WEST AFRICA

West Africa is composed of eighteen countries occupying various climate zones. The coastal region from Guinea-Bissau to Cameroon is characterized by abundant rainfall (with a rainy season of at least six months) and a thick forest of massive evergreen trees. A drier region, the savanna, lies five hundred miles north of the forest, and receives enough rainfall to sustain vast areas of rarer trees and grasses. The semiarid zone between the Sahara Desert to the north and the savanna to the south is called the Sahel, which in some years has a dry season of over nine months. North of the Sahel lies the Sahara Desert.

### Ancient West Africa

Eight thousand years ago, during Europe's Ice Age, the Sahara Desert supported large populations in a lush, fertile environment dominated by savanna grassland and woodland. Fruits and vegetables, sheep, goats, poultry, and cattle provided a reliable and abundant food supply that sustained a sedentary population as it grew and developed. Fishing populations flourished along numerous rivers and streams that flowed throughout the Sahara. As the Sahara's climate changed, becoming dry and mostly desert, migrations south to arable land increased the populations of sub-Saharan Africa.

Cultivation of crops in West Africa is theorized to have originated around the headwaters of the Niger River. Millet seems to have been the first important crop, and may have been eaten in a porridge. The techniques developed for crop cultivation of fruits, vegetables, herbs, and spices were indigenous to Africa. The Diola of Guinea-Bissau, for example, transformed most of the mangrove swamps lining a number of river estuaries into a network of paddy fields. Their techniques of dyking, desalinating, ridging, and transplanting antedate all European influence. The Yoruba and Bini and other Nigerian societies have lived in settled communities on the same sites for several hundred years, evolving agricultural systems that allow continuous cultivation of their soils without significant or permanent loss of fertility.

### Traditional Sources of Sustenance

In the forests of Ghana, as well as in Cameroon, traditional crops such as the cocoyam (taro) and plantain are successfully cultivated. These plants, together with raffia and oil palms, maize, cassava, African rice, and kola, thrive in the long rainy seasons, which run approximately nine months of the year.

Many West Africans who were not farmers were pastoralists or fishermen. Fish were eaten raw or pickled, fried, boiled, and prepared by "gumboing." Dried shrimp and crayfish are still essential ingredients in stews and sauces, some of which combine different types of fish with coconut milk and other ingredients. Crab, lobster, cod, mackerel, sole, pike, prawn, gilthead, eel, shrimp, sprat, flounder, carp, and other varieties of seafood provided

"fisher folk," such as the Twi of Ghana and the Muslim Bozo, with fish to sell at markets located well into the interior of the continent. In many West African cities these open-air retail markets were principally in the hands of women, who were economically independent traders.

The market streets were filled with stalls selling calabashes, palm oil, palm wine, ducks, chickens, fresh beef, mutton, and other meats, yams and yam fritters, guinea corn (sorghum) and millet beers, groundnuts, raw and cooked beans, thin brown cakes (said to smell like gingerbread), bean cakes, *karra* (meal dumplings), oblong bean buns called *jenkaraga*, and soups and stews. Some of the ready-made dishes included *enjibotchi* (rice with sauce), *ekoa* (durra [a sorghum grain] porridge), *killishi* (roasted meat, marinated and basted with oil, herbs, and spices), and *atchia-kara* (a yam and vegetable sauce ladled over chunks of beef, goat, and lamb).

An item used in Africa from antiquity, kola is indigenous to the forest zone of West Africa and is still preferred by Muslims who are prohibited from using alcohol and tobacco. It was valued as a refreshing stimulant and food by desert travelers during the trans-Saharan caravan trade and in the early stages of trade between the rain-forest regions, the Sahel, and beyond. In the sixteenth century, Askia Mahmoud supplied kola to his Songhai troops as an "energizer" before battle. Over forty species of kola are grown in the region between Sierra Leone and the Congo, with several varieties existing in Ghana alone. From ancient times, West Africans have also used different parts of the kola plant for treating swellings and fresh wounds. Ghanaians use it to reduce labor pain during childbirth and for treating guinea worm. In addition, kola nuts were used as primary flavorings in Coca-Cola and other beverages before kola substitutes were manufactured.

### Culinary Taboos and the Social Significance of Cattle Raising

Although chicken, lamb, mutton, and goat were raised and widely consumed, some societies adhered to taboos relating to one or all of these meats and their by-products. Egg consumption is still forbidden in some regions, as it is believed to turn young males into thieves and make childbirth difficult for women. The Mbum women of southwestern Chad, for example, do not eat any kind of eggs, chicken, or goat for fear of pain and death in childbirth, giving birth to abnormal or unhealthy children, or becoming sterile. In societies where goats were believed to have dietary value, they were bred specifically for their milk. In others, such as in the pastoral regions of the Sahel, goat milk is less favored than cows' milk as an item of trade, but is consumed by children and herders in the field. (Lactose intolerance among some West African peoples prevents them from drinking milk.) Lamb was usually grilled or barbecued and served at special feasts. Muslims prepared whole rams for the *Id el fetr*, a major festival.

Men preparing *fufu* in a mortar in Ghana. *Fufu* is used like dumplings or like pieces of bread for scooping up mouthfuls of stew. © LIBA TAYLOR/CORBIS.

Throughout Africa, cattle assumed a great importance in social, economic, and religious affairs. Cows were slaughtered and various beef dishes prepared for special occasions such as weddings, the naming of babies, festivals, or funerals. Cattle raising among the Bororo clan of the Fulani herdspeople (Fulani are dispersed throughout West Africa, from Senegal to Cameroon) is carried out by men who are charged with the herds' daily pasturing and watering, veterinary care, and seasonal movements. Women milk the cows and market the milk. The Bororo produce enough milk to support the family year-round, living primarily on dishes made with milk, cheese, and butter. They sell their milk products (or heads of cattle, if milk production decreases) to pay for other foods. Meat is not a staple part of the diet, but sometimes male or aged cattle are slaughtered and eaten on ceremonial occasions. The people of the northern regions, however, consume large amounts of barbecued beef.

Cattle are raised by the Mande peoples (numerous West African ethnic groups, including peoples of both the savanna and forest, that speak a Mande language)

primarily for prestige, dowry payments, and sacrificial offerings. For other peoples, cattle not only provide meat, hides, manure, and milk, they are also needed for pulling loads.

### The Legacy of Colonialism and Slavery

Slavery and colonialism sharply depleted the traditional abundance of meats and other foods after Europeans "discovered" Africa's wealth in the early sixteenth century. Colonialist control over African land and resources led to crop production almost exclusively for export. Profits from expanding agricultural exports went to foreign trading companies and colonial administrators, not to improve the lives of African peoples. "Cash crops," or the major exports, became palm oil from most of the coastal forest zone (a main source of lubricant for industrial machinery before the development of petroleum in the latter half of the nineteenth century), gum arabic from Senegal (a hardened resin substance extracted from acacia trees used to fix colored dyes in printed cloth in European textile factories), groundnuts from Guinea, coffee (the largest nonfuel export), and cocoa (primarily from Ghana, but Nigeria, Cameroon, and the Ivory Coast were also major producers). In the twentieth century, rubber from Firestone Tire plantations in Liberia was added to the list of exports.

The increases in production of export crops meant that production of food crops dropped and food prices rose. Sierra Leone, Liberia, and most of what was then called French West Africa were forced to import rice and other foods, even though they could grow their own. The market value of export crops also reduced the available land for staple foods at the expense of the native population. Another reason for the neglect of staple food crops was the depletion of the labor force. The slave trade drained an estimated forty million Africans from the continent between the fifteenth and nineteenth centuries. In addition, for those men between 18 and 60 years of age who remained, colonial law mandated that they labor a certain number of days for the state. Hundreds of thousands of young men left home to escape conscript labor laws in force in various parts of West Africa and found work on coffee, cocoa, and groundnut plantations in the Ivory Coast, Ghana, and Senegal.

In the late nineteenth and early twentieth centuries, urbanization and social change in some areas also pulled many people away from agricultural work, as the introduction of packaged and canned convenience foods made the traditional "from scratch" methods of food production and preparation almost obsolete. Still, West African holidays, feasts, and celebrations have been maintained, with some alterations, and continue to showcase the numerous dishes prepared with indigenous ingredients.

### Festive and Everyday Dishes

Celebrations and festivities mark numerous occasions: the start of seasonal rains, new planting season cere-

monies (between May and August), the “first fruits,” the call for blessings for good harvests, the harvest, the start of the hunting and fishing seasons, weddings, the birth of a baby (mothers are celebrated as well on this day), the baby-naming ceremony, pubertal initiation rites, festival dances, the completion of the building of a new home, religious holidays, and funerals. Huge feasts are the highlight of such celebrations, and numerous special main dishes, meats, breads, and snacks are prepared. *Banga* and *jollof* rice (a spicy Ghanaian dish of chicken, ham, stewed tomatoes, and onions), *egusi* (melon seeds) and peanut stews and coconut soup, tiger-nut mold (a favorite pudding made with fish and yams), bean and *abala* (ground rice) puddings, roasted and barbecued meats, cassava dumplings (prepared with the leaves of the fluted pumpkin), *tiébou dienn* (pronounced “cheb-oo jen,” Senegal’s national dish, a fish and rice stew made with yams, okra, eggplant, cabbage, and chili peppers), vegetable side dishes (such as *akee* cooked with two or three varieties of greens), coconut candy, *chinchin* (twisted cakes), *abacha mmili* (cassava chips), *ipekere* (plantain chips), *meensa* (millet cakes), and banana fritters (rolled in groundnuts and sorghum or corn flour or cassava meal before frying) are just a few of the items on the celebration menus. *Poulet yassa*, chicken marinated in a lemon and onion mixture then grilled or sautéed, is one of Senegal’s most famous dishes.

These are foods enjoyed in most of the countries within the Sahelian zone today (Mauritania, Senegal, The Gambia, Mali, Guinea-Bissau, Burkina Faso, Niger, Chad, and Cape Verde), where some of the dominant staple foods are millets, Bambara groundnuts, yams, Asian rice, sorghum, cassava, cowpeas (black-eyed peas; there are forty varieties), sesame (mixed with wheat for biscuits, used in chicken recipes, and in sesame *sucre* [sugar], a children’s snack), maize, peanuts, and fonio (for hot breakfast cereal). Dominating the diets of the coastal countries (Guinea, Sierra Leone, Liberia, Côte d’Ivoire [Ivory Coast], Togo, Ghana, Benin, Nigeria, and Cameroon) are cassava, Asian rice, maize, cowpeas, lima beans, pigeon peas, sorghum, peanuts, plantains, cocoyam (taro), and yams. Plantain is the basic ingredient for many popular snack foods throughout Côte d’Ivoire, and, with bananas, bridges the gap between the dry season and harvest months of January to May, when other staples are unavailable or scarce. The cocoyam is rapidly becoming a major staple in coastal communities, while cultivation of yams in producer countries has been gradually decreasing. Nigeria is the world’s largest producer of cocoyam, followed by Ghana. Served by themselves, or mixed with plantains, yams, or cassava and other ingredients, cocoyams are used to make the traditional dish called *fufu* (also *fou fou*): the staples are cooked and pounded into a smooth soft dough used to make dumplings.

In addition to being popular foods, cocoyams and yams have always carried social and cultural significance. In Nigeria, the cocoyam festival, *Alube*, is celebrated an-

nually in May. Yams are intertwined in the social, cultural, and religious life of the farming communities where they are the major crop. In remote areas of West Africa, yams were an important status symbol, conferring prestige on families who consumed large quantities. Many customs dictate that yams should be used to wean babies, and special yam dishes are prepared for birth rituals and the naming ceremony for children. In some societies, yams are also important foods for funerals as ceremonial offerings to the gods and to the spirits of the departed, in others as food during the funeral feasts.

Throughout West Africa, the yam is revered by many traditional societies including the Ibo of eastern and midwestern Nigeria. Although many of their customs have been lost or modified due to European influence, it is believed that the Ibo are more devoted to yam cultivation than any other yam producers. Their religious devotion to the food has prevented its displacement by other crops.

The New Yam Festival is, in many West African regions, the most important celebration of the year. The annual festivals are associated with planting but more particularly with the yam harvest. Some of the groups that celebrate the festival include the Ashanti of Ghana, the Ibo and Yako of eastern Nigeria, the Yoruba of western Nigeria, the peoples of the eastern Ivory Coast, the Ewe of Togo, the people of Benin, the Tiv of the Benue region of northern Nigeria, and the Kalabari of the eastern Niger Delta.

### Other Indigenous Foods

Yams can be stored for six to nine months, but if they begin to run low, they are usually supplemented by fruits, seeds, and nuts that grow in abundance at different times of the year. In various regions of West Africa, these crops include the African breadfruit, the African pear, the incense tree, the star apple, the African mango, the shea butter tree (*Vitellaria paradoxa*, which produces a nutlike fruit—57 percent of its seed’s weight is oil), various species of gourd (many have yamlike roots that grow deep underground), and the cultivated species of sword lily or corn-flat, the *Leguminosae*, which produces tubers and edible roots, and the all-purpose baobab tree.

The baobab grows wild in the savanna regions of Mali and other areas of West Africa. Rope was made from its bark and medicines were manufactured from extracted liquids as well as from its dried leaves; the dried leaves were also used as a thickener for stews. In addition, its fruit is not only a great source of vitamin C, but is also used to make refreshing drinks containing tartaric and other acids. A meal for making bread was derived from this plant, as was a red dye.

Sorghum, another indigenous food crop, also provides a red dye that is rubbed into animal skins to make red leather, and its stems yield large amounts of sugar. Sorghum is probably one of the world’s most versatile

food crops with undeveloped genetic potential. In Nigeria, young children eat the yellow varieties of sorghum to prevent blindness because their diets are deficient in vitamin A. The most common food prepared in Nigeria is *tuwo*, made by stirring sorghum flour into hot water and allowing the thick paste to cool and gel. Once cooled, *tuwo* is cut or broken up and eaten with soup. In West Africa it is generally known as guinea corn, and the grains of certain varieties are popped like popcorn. Sorghum grain is made into flour for a thick pancake batter fried in groundnut oil; sorghum beer is a favorite beverage consumed at wrestling matches as *burkutu*, an alcoholic gruel, or as *pito*, with the sediment removed. *Dawaki* are flat fried cakes made with a mixture of sorghum and bean flours, and sometimes accompany soups. A flour and water batter, *akamu*, is used to flavor and thicken porridges and cereals.

Sorghum, rice, maize, yams, plantains, cassava, and taro (cocoyam) are staples along with common ingredients such as onions, tomatoes, palm fruits, *egusi* and other melon seeds (used for thickening), okra, pumpkin, coconut, coconut milk, and a variety of nuts. Fish, meat, and vegetable dishes are heavily seasoned with numerous hot peppers and spices, such as Guinea pepper grains (*melegueta*), spicy cedar (called *atiokwo* in the Ivory Coast; the seeds are roasted, ground, and used in soups or with leafy vegetables), tea bush (known as *an-ghonto* in Sierra Leone; its fragrant leaves are used to flavor meat dishes and vegetable, *egusi*, and palm nut soups), African locust bean (harvested, boiled, and fermented to produce *dawadawa*, an indispensable condiment in Nigerian and Cameroonian cuisine), and West African black pepper (known as *fukungen* to the people of The Gambia and Senegal). Several oils are used in preparing West African dishes, such as groundnut (or peanut, sometimes preferred in stews), melon seed, sesame seed (*gingelly* or *gingili*), coconut, corn, shea butter, and palm, the favorite because it imparts a reddish color to foods. Cooking methods include frying, simmering or boiling, roasting and steaming (foods are steamed in banana, plantain, miraculous berry, cocoyam leaves, or corn sheaths), and baking, or combinations of two or three of these methods. Broiling was added in the twentieth century.

Two to three very large meals are prepared and consumed daily, and West Africans eat until they are full. Breakfast can consist of *pap* (or *ogi*, a hot beverage made with corn meal, milk or sour milk, and sugar), *akara* (bean cakes made with black-eyed peas or other beans, water, salt, onions, and peppers, then fried in peanut or palm oil), *moi-moi* (steamed bean pudding, made with black-eyed peas or other beans), roasted or fried plantains, and tea or coffee. West Africans enjoy *gari* (the dried and ground form of cassava) with soup for lunch, along with okra, *egusi* or *agbono* soup (seeds from the *egusi* melon are toasted and ground; *agbono* are the dry seeds from the African mango, ground to a smooth paste before using), and *fufu* (pounded yam). All soups contain various greens,

such as *ukazi* and cassava leaves, and smoked or dried shrimp and crayfish. For dinner, there is *jollof* rice or coconut rice with roasted meats, boiled rice and a chicken, beef, or fish stew (or palm nut or pepper soup) containing okra, cabbage, groundnuts (or peanuts), and other ingredients. Vegetable side dishes, including beans and rice or rice garnished with fried plantains, are very popular. An indigenous Ghanaian dish, *kenke*, is steamed pudding made with fermented maize pulp; its two varieties are served with soups and stews. Occasionally fruits are served as appetizers, but traditionally all dishes are served at the same time rather than in courses. Fruits, nuts, and snacks, such as *chinchin* (twisted cakes sold by vendors along roadside markets), are sometimes eaten between meals.

### Summary

As host for centuries to fortune hunters, colonialist regimes, and migrations from Europe and other countries, West Africa has been perceived as the recipient, not the provider, of cuisine and culture. Even as French and other foreign languages began to blend with those native to the continent, thereby changing the names of certain dishes, and as minor changes in ingredients were made in those dishes (by way of foreign influence), West African cuisine remained a significant cultural force.

Archeological excavations, together with new studies on Africa's agricultural and culinary past, demonstrate that Africa had many indigenous crops. Unfortunately, emphasis is too often placed on foods brought into Africa during the period of slavery and colonization rather than on indigenous foods consumed domestically or exported to foreign countries, and most studies limit African agriculture and diet, prior to European influence, to a small number of indigenous foods: yams, cowpeas (black-eyed peas), sorghum, millets, okra, some bush greens, and whatever items were gathered. Watermelon, *akee* (*Blighia sapida*; also *ackee* or *achee*, a bright-red tropical fruit with black seeds and a creamy white flesh), tamarind, bottle gourd, fluted pumpkin, *egusi* melon, sesame, and one or two other beans have been added in a few studies.

In Volume I of its *Lost Crops of Africa*, the National Academy of Sciences reports that Africa has produced more indigenous cereal grains, including its own species of rice (nutritionally superior to Asian rice), than any other continent. Among Africa's more than two thousand currently known native food plants are grains, such as African rice, pearl and finger millets, and fonio; cultivated fruits, such as *balanites* (desert dates), butterfruit (*africado*), horned melon, ziziphus (Rhamnaceae, the buckthorn family) and *kei* apple; wild fruits, such as chocolate berries, figs, custard apples, grapes, gingerbread plums, and star apples; vegetables such as amaranths, spirulina (a nutritious blue-green algae of fresh and brackish waters), edible mushrooms, oyster nuts, Ethiopian mustard, gherkins, mock tomatoes; legumes such as *marama*, locust and sword beans, grass peas and guar; roots and tu-

bers such as *anchote* (*Coccinea abyssinica*), Hausa potatoes, tiger nuts, several varieties of yam, and vigna roots, and a number of spices and herbs.

These foods are endangered by “botanical colonialism,” the export system of “cash crops” and “one-crop agriculture” imposed on West Africa and the rest of the continent by European colonialism. In addition, “structural adjustment programs” of the 1980s, designed by the World Bank and the International Monetary Fund to increase the role of exports in the economy and reduce Africa’s deepening debt crisis, have actually intensified low agricultural productivity for domestic consumption. Poor families, in an effort to meet urgent food needs, often intensively cultivate lands and forests for subsistence or exports, frequently in areas that once yielded ancient crop species or medicinal plants, or those that are sometimes erosion-prone, where crop yields drop severely after a couple of years. Food shortages, famine, disease, and widespread poverty are the result.

West Africa has been a major contributor to world cuisine in terms of the migration of its indigenous crops, methods of production of those crops, and culinary customs. Very few of Africa’s currently known native food plants have received the recognition or research deserved and warranted for so vast a larder. The scientific community has not been able to provide an exact count of foods actually native to the continent nor the age of most of its crops. The history of the continent’s flora is, therefore, virtually unknown. As with environments threatened with endangered species, Africa’s indigenous agricultural pantry is gradually dwindling due to lack of research and interest. Many biases exist against native African foods, biases that have kept alive perceptions of the inferiority of African crops. It is therefore hoped that there will be an eventual understanding and appreciation of Africa’s endangered agricultural species, as they have much to offer, not only to Africa but the rest of the world as well in terms of solving major hunger, disease, and energy problems.

**AGRICULTURAL RESEARCH.** Agricultural research has occurred continuously since humans began shifting food acquisition methods from hunter-gatherer to agrarian. The early goal of agricultural research was simply better methods of producing food. As humans and agriculture progressed, research widened to control of diseases and pests, better cultivars, productive fields or animal rearing facilities, improvement of food crops, and basic biological understanding of plants and animals. The early studies were empirical, that is, trial and error. Nevertheless, these were the forerunners of agricultural research and in many ways the forerunners of many forms of scientific investigation.

### Beginnings

Most people place the beginnings of formal agricultural research in the late eighteenth century to the mid-nineteenth century. This relatively long initial phase was caused by several factors. First, many of the other basic sciences were in an early developmental stage. In fact the early agricultural scientists were trained chemists applying their skills to food production. Secondly, governments were reluctant to provide funding for agricultural research. In the United States both George Washington and Thomas Jefferson advocated formal agricultural re-

search as a fundamental component of the newly developed country. However, Congress did not share either president's feeling and did not support a formal agriculture department until 1862. The U.S. Department of Agriculture did not achieve cabinet status until 1889.

Third, many of the world's great universities had not yet been founded or were also in early stages of development. The first colleges involved in agricultural research in the United States were Harvard, Yale, and Princeton. Several of the early endowed chairs in universities were in chemistry, agriculture, or a combination of the two. Fourth, agricultural principles developed were often not applicable to farms or crops in other parts of a country or continent. Thus an initial credibility problem existed with much of the early agricultural research. In the mid-1800s the concept of an experiment station developed in Europe. Some authors credit the Germans with development of the experiment station, while others credit the British. Regardless of the location of the first stations, the concept was to develop agricultural research sites near areas of agricultural production so results would be applicable to the local areas. This concept became common in all areas of agricultural production.

Justus von Liebig is often credited with writing the first book on agricultural research, *Organic Chemistry and Its Applications to Agriculture and Physiology*, published in both Germany and England in 1840. Liebig was an agricultural chemist in Giessen, Germany, one of the first experiment station sites. Liebig also established courses in agricultural chemistry and provided a site for foreign students to study under his tutelage. Numerous students from across Europe and the United States studied under him. The model Liebig developed for research sites near production areas, student training, and course offerings remained the standard for agricultural research around the world in the early twenty-first century.

### Developments in the United States

The U.S. government did not establish a formal agricultural research agency until the middle part of the nineteenth century. Early agricultural research, from 1836 to 1862, was conducted by the U.S. Patent Office, which received, on an irregular basis, funds from Congress for specific purposes. Scientists trained in Europe were hired as faculty members by many of the universities and by other nongovernmental groups, such as the Smithsonian Institution. Thus it seems clear that universities in Europe, particularly in Germany and England, were the first to establish formal agricultural research programs.

As the scientific disciplines of chemistry and biology developed, those principles were increasingly applied to food production. In many cases chemical assays and principles were established in direct response to needs in the food and agriculture industries. In the second half of the nineteenth century agricultural research became a recognized discipline in institutes of higher education. The Hatch Experiment Station Act of 1887 established a for-

mal linkage between the U.S. Department of Agriculture, which would supply funding, and state colleges of agriculture, where the research would be conducted. This collaboration between states and the federal government was an important model in governmental relations.

Through the first sixty to seventy years of the twentieth century, Hatch funds were sufficient to conduct research and to train students at universities. However, late in the century Hatch funding received no increases, and the funds diminished in real terms. In the twenty-first century, university scientists working in agriculture must compete for funds from a variety of funding sources, mostly federal government programs, by writing competitive proposals. Congress in collaboration with the president provides funds for the various federal research programs. Thus at times funding for research topics is influenced by political motivations instead of by the common good. Even with staffs and consultants well versed in current topics, this approach diminishes the dialogue on the most important topics that require research support. This change in research funding has positive and negative attributes. On the positive side, only the best research, on topics that have far-reaching implications and those that will have the largest impact on agriculture and society, is conducted. On the negative side, minor agricultural industries rarely receive any of this funding, and development of new opportunities in agriculture is difficult.

E. John Russell (1966) described five phases of agricultural research in Great Britain. While the years may differ, the concepts and general timing are similar to other parts of the world. Phase one began in the late sixteenth century with Francis Bacon and was characterized by numerous individuals conducting research in ancillary areas to agriculture without communication among themselves. This period lasted until the end of the eighteenth century.

The second phase coincided with the emergence of chemistry and lasted until the mid-nineteenth century. Numerous nongovernmental groups were established during the period to promote agriculture, and several universities established formal programs in agricultural sciences. The third phase lasted until the early twentieth century and included establishment of extension activities in university programs as well as expansion of teaching. The fourth stage was a short but important period because of the expansion of experiment stations, research funding from governments, and recognition of the role of agricultural development as an economic development tool. This phase lasted from 1920 to 1930. The fifth phase has lasted into the twenty-first century. Russell described this phase as the time of governmental laboratories and dissociation from farmers and their needs. While Russell's view is rather cynical, many farmers share his point.

As large, multinational companies became involved in agricultural research, much of the generated research

results became proprietary and focused on generation of revenue. However, the range of products developed during the twentieth century was extraordinary, ranging from corn syrup to lecithin and resulting in products that literally changed lives. Breakfast cereals, sliced white bread, hot dog buns, soybean meal, and more changed the way people lived in developed countries and offered the promise of alleviating hunger and malnutrition in the remainder of the world. Agricultural research in universities focused on production of crops, both plant and animal, and on improving efficiency of production. Agricultural engineers led the Industrial Revolution and are rapidly applying space-age technology to tractors. Advanced biological lines of research, including microbiology, biochemistry, molecular biology, and developmental biology, are routine in agricultural research laboratories in the twenty-first century. Practical agricultural research funding, however, is diminishing.

Agricultural research was one of the early areas of formal scientific investigation and remained the foundation for many forms of research in the twenty-first century. Results from this research led to high-quality foods that are moderately priced, significant improvements in health, elimination of various diseases, far-reaching increases in cognitive function, and many other benefits to society.

**AGRICULTURAL WORKERS.** In the United States, workers in agriculture include agricultural inspectors, graders and sorters, and farmworkers. While some agricultural workers find permanent, full-time positions, most will work in temporary, low-paying jobs that

are seasonal and often require seven-day workweeks with days that begin before sunrise. They may work indoors or outdoors. Most work with food crops or animals. However, increasing agricultural mechanization, consolidation of farms, and urbanization have led to less growth in the number of agricultural jobs in the United States. Growth in landscape and horticultural services will require a shift to fill the need for more workers in horticulture and landscaping. According to the United States Bureau of Labor, the number of jobs in agriculture was expected to grow more slowly than the average for all occupations during the 2000–2010 period.

### **Agricultural Inspectors**

Most agricultural inspectors work in full-time, permanent positions for the federal and state governments. Inspectors frequently examine food crops, livestock, and food processing equipment and facilities for compliance with laws and regulations that govern health, quality, and safety. Inspectors also examine nursery and greenhouse crops. In order to control or eradicate pests and diseases, they collect samples of food or plants and send them to a laboratory for further examination and analysis.

### **Graders and Sorters**

Graders and sorters of agricultural products spend their workdays grading, sorting, and classifying food and other

agricultural products such as buckwheat hulls, pickles, olives, nuts, and apples. Fresh-picked fruits and vegetables must be examined and sorted by size, weight, color, or quality before packaging for markets.

### **Farmworkers**

Farmworkers make up 90 percent of all agricultural workers. However, according to the Economic Research Service, the number of farmworkers is difficult to determine since they tend to live in unconventional housing, or are undocumented foreign immigrants who avoid enumerators. Farmworkers include laborers who work with food, greenhouse, and nursery crops, and also caretakers of farm and ranch animals. Compared to most wage and salary workers, farmworkers tend to be younger, less educated, never married, and non-U.S. citizens. Most are male and Hispanic or belong to a minority. Most farmworkers live in poverty. Between 1999 and 2000, the real average weekly earnings of hired farmworkers decreased from \$331 to \$319 for full-time workers and from \$289 to \$280 for all hired farmworkers—and the downward trend seems to be continuing.

***Migrant farmworkers.*** Migrant farmworkers make up a large segment of all farmworkers in the United States. Migrant workers travel across state or county boundaries to do agricultural work of a seasonal or other temporary na-

ture, and often must be absent overnight from their permanent place of residence. In 2000, 36 percent of hired farmworkers were not United States citizens. Almost 78 percent of the non-U.S. citizens working as hired farmworkers were employed in the West, where they accounted for 63 percent of the hired farmworker force. Crop production accounted for 72 percent of migrant farmwork.

Migrant and other farmworkers often work physically exhausting schedules: seven days a week, thirteen hours per day, in rain, heat, and high humidity. For example, while detasseling corn in Illinois in July, a group of migrant workers will likely experience insect bites, heat exhaustion, injury, fatigue, and exposure to pesticides and fertilizers. Workers earn minimum wage and may be provided with temporary housing and access to local health care. Some workers must contend with harassment when local residents mistrust the workers. Language is a barrier, especially for older workers who have not learned English. Families that travel throughout the year must keep up with schoolwork. Local school systems may provide summer school, or students may use the Internet to stay in touch with their courses at home. Sometimes, nonprofit groups will provide migrant schoolchildren with special activities such as swimming classes, library access, or tutoring.

Migrant workers have not always received the help they needed. In the 1960s—at the same time as the civil-rights movement and opposition to the Vietnam War—an effort was made to organize farmworkers in order to improve the quality of their lives. César Chávez, a migrant worker, organized agricultural workers in a successful bid for higher wages, better working conditions, and access to social services such as citizenship classes, immigration advice, and welfare counseling. In the 1970s, the United Farm Workers of America (UFWA) had 150,000 members. By the late 1990s, illegal labor or legal “green card” workers had diminished the power of the UFWA. Few twenty-first-century agricultural workers are members of a union. Some migrant agricultural workers do not have legal authorization to work in the United States.

**AGRICULTURE, ORIGINS OF.** The last thirty years have seen a revolution in our understanding of the origins of agriculture. What was once seen as a pattern of unilateral human exploitation of domesticated crops and animals has now been described as a pattern of co-evolution and mutual domestication between human beings and their various domesticates. What was once seen as a technological breakthrough, a new concept, or “invention” (the so-called Neolithic revolution) is now commonly viewed as the adoption of techniques and ultimately an economy long known to foragers in which “invention” played little or no role. Since many domesticates are plants that in the wild naturally accumulate around human habitation and garbage, and thrive in disturbed habitats, it seems very likely that the awareness of their growth patterns and the concepts of planting and tending would have been clear to any observant forager; thus, the techniques were not “new.” They simply waited use, not discovery. In fact, the concept of domestication may have been practiced first on nonfood crops such as the bottle gourd or other crops chosen for their utility long before the domestication of food plants and the ultimate adoption of food economies based on domesticates (farming).

The question then becomes not how domestication was “invented” but why it was adopted. What was once assumed to depend on cultural diffusion of ideas and/or crops is now seen by most scholars as processes of independent local adoption of various crops.

#### Patterns of Domestication

The domestication of the various crops was geographically a very widespread series of parallel events. Some scholars now recognize from seven to twelve independent or “pristine” centers in which agriculture was undertaken prior to the diffusion of other crops or crop complexes (although many of these are disputed) scattered throughout Southwest, South, Southeast, and East Asia; North Africa and New Guinea; North, Central, and South America; and possibly North America. As the earliest dates for the first appearance of cultigens are pushed back; as individual “centers” of domestication are found to contain more than one “hearth” where cultivation of different crops first occurred; as different strains of a crop, for example, maize or rice, are found to have been domesticated independently in two or more regions; as an increasing range of crops are studied; and, as little-known local domestic crops are identified in various

regions in periods before major crops were disseminated, the number of possible independent or “pristine” centers of domestication is increasing, and the increase seems likely to continue.

### Early Domestication of Crops

Combining patterns provided by various scholars (see the bibliography) suggest that major domesticates appear in Southwest Asia or in the Near East (wheat barley, lentils) by 9,000–12,000 B.P. or even earlier; in Thailand (rice) between 12,000 and 8,000 B.P.; in China (millet, soybeans, rice) ca. 9,500 B.P.; in Mesoamerica (squash, beans, and maize) between 10,000 B.P. and 5,500 B.P.; in South America (lima beans and peppers) by ca. 8,000–10,000 B.P. and, with less certainty, potatoes and manioc by 6,000 B.P.; and in North America north of Mexico (sunflowers, may grass, chenopods, sump weed, and marsh elder) by 4000–5000 B.P.; in North Africa (pearl millet, sorghum) by 5500–6800 B.P.; in Southeast Asia (taro) by 8000 B.P. and possibly much earlier. (Root crops are presumed to have had even longer histories of domestication in the moist tropics but they are poorly preserved and difficult to document archaeologically.)

As an example of the regional complexity of incipient domestication, there may have been three centers of domestication at three altitudes in South America: a lowland complex involving manioc and sweet potato; a mid-elevation complex involving amaranth, peanut, jicama, and coca; and a high-elevation group including potato and other lesser tubers such as *ullucu*.

The agriculture of particular preferred crops also spread widely by diffusion or population movement in some areas in the prehistoric period. In perhaps the best known patterns of diffusion of agricultural economies (or displacement of indigenous hunter-gatherer populations), Middle Eastern farming economies had spread to Bulgaria by 7500 B.P.; to Italy by 7000 B.P.; and to Britain by 6000–5000 B.P. Maize diffused very widely in North and South America from Mesoamerica (apparently without the significant spread of people); and rice cultivation diffused throughout South, East, and Southeast Asia.

Despite its geographical dispersal, the adoption of the various domestic crop economies occurred within a narrow time span, between about 10,000 and 3,000 B.P. The human population entered a relationship with many different plants at about the same time, implying that human activities were the prime motivator of major economic change and entry into mutual domestication in each instance.

Domestication (genetic manipulation of plants) and the adoption of agricultural economies (primary dependence on domestics as food), once seen as an “event,” are now viewed as distinct from one another, each a long process in its own right. There is often a substantial time lag between incipient domestication of a crop and actual dependence on it. That is, the adoption of farming was

a gradual quantitative process more than a revolutionary rapid adoption—a pattern of gradually increasing interaction, and degrees of domestication and economic interdependence.

Moreover, the adoption of agriculture was, by all accounts, the coalescence of a long, gradual series of distinctive and often independent behaviors. Techniques used by hunter-gatherers to increase food supplies, long before farming, included the use of fire to stimulate new growth; the protection of favorite plants; sowing seeds or parts of tubers without domestication; preparing soils; eliminating competitors; fertilizing; irrigating; concentration of plants; controlling of growth cycles; expansion of ranges; and ultimately domestication. By this definition, domestication means altering plants genetically to live in proximity to human settlements, enlarging desired parts, breeding out toxins, unpleasant tastes, and physical barriers to exploitation—in short, getting plants to respond to human rather than natural selection.

### Dependence on Crops

Almost all authorities describe a gradual increase in the quantitative dependence on domesticated crops. Most also see a quantitative shift from high-quality to low-quality resources (a reduction in the variety and density of essential nutrients, calories, protein, vitamins, minerals, and fatty acids per unit of bulk, desirability of foods, and ease of exploitation). Most also describe a movement downward in the trophic levels of foods exploited. A common theme in almost all discussions of the origins of agriculture is the idea of increasingly “intensive” exploitation of foods (the use of increased labor to exploit smaller and smaller areas of land).

This sequence of events commonly first involved a focus on an increasing range (a “broad spectrum”) of low-priority wild resources, increasing the efficiency in which space was utilized—a shift from economies focused on comparatively scarce but otherwise valuable large animals and high-quality vegetable resources to one in which new resources or different emphases included smaller game, greater reliance on fish and shellfish, and a focus on low-quality starchy seeds. There is a clear and widespread appearance of and increase in apparatus (grindstones for processing small seeds, fishing equipment, small projectile points) in most parts of the world before the adoption of agriculture, which cannot be a function of differential preservation.

Ultimately the spectrum of exploitation seems to have narrowed again as populations shifted toward more complete modification of landscapes to permit increased dependence on particular low-priority but calorically productive starches that could be obtained in large quantities per unit of space and then stored. Such modification of the land to focus on the quantity of calories per unit of space by promoting staple crops would then eliminate some calorically marginal foods, resulting in a loss of dietary variety and of some nutrients. (The major

staples—rice, maize, wheat, barley, potatoes, sweet potatoes, manioc, and taro—all cause dietary deficiencies when relied on too heavily as the sole basis of a diet. The deficiencies are likely to be exacerbated by dry storage, which destroys C and B-complex vitamins.)

### Intensification of Resource Use

The intensification can probably be seen best through the eyes of optimal foraging theory, much of which has focused on caloric returns for each unit of labor provided by various foods, and has argued that human groups will go first for high-ranking resources (those that yield high returns for a unit of work including preparation). Repeated studies of comparative efficiency of food-gathering techniques in various parts of the world have routinely reported that human populations should prefer resources such as large game, which, when available, can be exploited with great efficiency. Populations turn to increasing reliance on lower-ranking, that is, less efficiently exploited, resources (small game, shellfish, most nuts, individually caught fish, and small seeds) only as those of higher rank disappear or become so scarce that the time involved in finding them becomes prohibitively high (for example, as large game becomes scarce). Such calculations by scientists do not predict the behavior of individual populations perfectly (presumably because other factors such as local food preferences or inertia come into play). But they do dramatically conform to the broad trends in prehistory relating to a Paleolithic-Mesolithic-Neolithic sequence or its equivalents in the New World. And they suggest that this sequence of economic changes is one of declining efficiency in resource exploitation.

Resources used increasingly in the intensification of individual units of land—the so-called broad-spectrum revolution—typically provided fewer calories per unit of labor than the comparative emphasis on large animal exploitation that preceded them. Small seeds such as wheat, barley, rice, and maize typically are among the least productive resources (and among the lowest priority as well in taste and quality) and would presumably have come into use only as preferred resources disappeared or became prohibitively scarce. Seasonal seeds, although potentially harvested quickly and in large quantity, typically involved intensive processing and the labor of storage as well as significant storage losses. A significant point is that the adoption of low-ranking resources depended not on their availability but on the declining availability of higher resources. Cereals were adopted not because they were or had become available but because preferred resources such as large game were becoming less available.

The major cereals are relatively inefficient to exploit and process, as demonstrated by Kenneth Russell with specific reference to the Middle Eastern cradle of wheat and barley cultivation. Agriculture, therefore, may not have been “invented” so much as adopted and dropped repeatedly as a consequence of the availability or scarcity of higher-ranked resources. This pattern may in fact be

Working the fields in ancient Egypt, as depicted in the Book of the Dead of Heruben, circa 1069–945 B.C.E. © GIANNI DAGLI ORTI/CORBIS.

visible among Natufian, or Mesolithic, populations in the Middle East whose patterns of exploitation sometimes appear to defy any attempt to recognize, naively, a simple sequence of the type described above.

Technological changes were motivated by necessity or by demand, not by independent invention or technological advance. In a trend toward declining efficiency, one does not adopt new technologies simply because they are available. Such innovations may well be held in reserve until changing conditions render them the best remaining alternatives. Demand-side economics seems to have powered most of economic history; Malthusian or supply-side economics, with supply independent from demand, became the predominant pattern only when the rise of social classes prevented the needs of the poor from generating any economic “demand”—which implies not only need but entitlement (the ability to command resources).

Various sources point out, however, that such “intensification” occurred in parallel among incipient farmers and populations such as those of the West Coast of the United States, which developed an intense focus on storing starchy staples (such as acorns) but never domesticated them. The two activities may be distinguished, and centers of origin of domestication may be defined, less by human knowledge or intent as by the flexibility or recalcitrance of the intensively harvested plants toward incipient domestication. Some resources such as wheat respond readily to human manipulation; others such as acorns/oak trees defy it.

Increased demand results from population growth, climate change, and socially induced demand. Mark Cohen argues that population growth and increasing population density—or a combination of population growth

and declining availability of preferred foods, which result in “population pressure” or an imbalance between population, resources, and prevalent food choices and extractive strategies—may be the main trigger of relevant economic changes. Such increasing density is ultimately traceable to the Pleistocene with the gradual density-dependent closing of cultural systems as increased density permitted groups to switch from exogamy to endogamy. According to this model, the widespread parallelism of different regions is based on the power of population flux (movement between groups) to equalize population pressure from region to region. The model has been criticized for, among other reasons, relying too much on flux as an explanatory necessity, for having the wrong time scale, and for underplaying the role of climate change.

A second category emphasizes the role of post-Pleistocene climate change in both facilitating and demanding exploitation of plants amenable to domestication. It has been argued, in fact, that farming would have been essentially impossible during the Pleistocene, but almost mandatory, at least in a competitive sense, in the Holocene. This model may provide a more powerful explanation of the regional parallelism of intensification in time than a purely population growth/flux model. The climate-based model has been criticized, however, as ignoring the fact that climate and environmental changes are zonal and therefore could not, of themselves, produce parallel economic changes in different environments undergoing different kinds of change.

A third major category that explains increased demand suggests that it resulted from enhanced social and political demand preceding and accompanying intensification. The problem is that such explanations, unless combined with data on population growth or climate change, fail to explain the parallel emergence of complex social forms.

### **Agriculture and the Decline in Health, Nutrition, and Food Security**

Agriculture commonly has been associated with a number of social features: reduced territories, more marked social boundaries, further closing of mating systems; greater territoriality and formal definitions of property; complex social and political organization; more defined concepts of property; food storage; and sedentism. Moreover, agriculture has until recently been considered the cause or enabler of these altered social institutions. These features are only loosely bound, may be separated by long spans of time, and may occur in any of various sequences. For example, sedentism in many regions occurs long before domestication (as in parts of the Middle East), but in the New World the reverse often occurs—domesticates appearing long before settled reliance on those domesticates. Social complexity may commonly follow the origins of agriculture but precedes it in many parts of the world and, as mentioned above, occurs without domestication in some parts of the world.

### **Changes in Health**

What was once interpreted by researchers as a transition toward improving human health, nutrition, reliability of the food supply, greater ease of food procurement, and greater longevity is now viewed as the start of declining health, nutrition, and efficiency of labor, probably declining longevity, and perhaps even declining security of food supplies. It is now commonly accepted that the adoption of farming economies and sedentism resulted in declining health and nutrition. The conclusion is based on triangulation from three sources: contemporary observation of hunting and gathering versus farming societies; theoretical patterns of nutrients and parasites in nature; and paleopathology, the analysis of health and nutrition in prehistoric skeletons representing different periods of prehistory. Many sources have found parallel trends toward declining health in prehistoric populations but challenges to quantitative methods, interpretations of some evidence, and some specific conclusions in paleopathology have been offered. Observed paleopathological trends commonly accord with expectations from other lines of evidence.

It seems probable from epidemiological considerations—and it is clear from paleopathology—for example, that farming, large concentrations of population and sedentism, the accumulation of human feces, and the attraction of stored foods to potentially disease-bearing animals markedly increased parasite loads on human populations. The increase in the prevalence of visible periostitis, osteomyelitis, treponemal infection, and tuberculosis in skeletal populations conforms both to ethnographic observations and models of probable disease history. The reduction of wild animal meat in the diet with the increasing focus on vegetable foods may initially have reduced the likelihood of food-borne diseases (of which animals are the major source). But the domestication of animals, their crowding, and their continuing proximity to human populations are likely to have raised meat-borne infections to new highs and seems responsible for epidemic diseases in human populations, many of which began as zoonotic (animal-borne) disease shared by people and domestic animals.

### **Consequences of Agriculture**

Sedentism and farming resulted in declining quality of nutrition (or at least in the decline in the quality of nutrients available to the human populations). Indeed, some researchers have extolled the virtue of hunter-gatherer diets. Agriculture is likely to have resulted in a marked downturn in food diversity and food quality, and ultimately to a decline in nutrition. An increase in cumulative neurotoxins may have occurred as farming was adopted, the latter despite the fact that domestication itself may have bred toxic substances out of foods.

Agriculture also seems to have resulted in a change in the texture of foods toward softer foods, resulting in a decline in tooth wear but an increase in dental caries

and a reduction in jaws and jaw strength. A significant advantage of soft foods based on boiling in ceramic pots, a practice largely restricted to sedentary populations, may have been the increasing potential for early weaning of children and improved food for toothless elders. But early weaning to cereals as opposed to a diet of mother's milk is well known to have serious negative effects on childhood nutrition, infection, and survival.

A dramatic increase in iron deficiency anemia (porotic hyperostosis and cribra orbitalia) is associated everywhere in the archaeological record with both sedentism, infection, and new crops. The trend is also predictable in nature, and may be observed in contemporary populations. The increased anemia probably resulted primarily from a large increase in iron-robbing hookworm associated with sedentism and with the sequestering by the body of its own iron as protection against bacterial disease.

The declining health that came with the advent of farming is also reflected in (but not universally) childhood declines in stature, osteoporosis in children, decreases in tooth size (as a result of declining maternal nutrition), and tooth defects.

Whether the adoption of broad-spectrum foraging, agriculture, storage, and sedentism increased or decreased the reliability of food supplies (and whether sedentism is itself a consequence of choice permitted by new resources or necessitated by them) is a matter of some debate. For example, it is not clear whether broad-spectrum foraging increased reliability by expanding the resource base, or decreased reliability by focusing exploitation on what had once been emergency resources.

Domestication, sedentism, and storage appear to have evened out potential seasonal shortages in resources, but they may also have reduced the reliability of the food supply by decreasing the variety of foods consumed; by preventing groups from moving in response to shortages; by creating new vulnerability of plants selected for human rather than natural needs; by moving resources beyond their natural habitats to which they are adapted for survival; and by the increase in post-harvest food loss through storage—not only because stored resources are vulnerable to rot, or theft by animals, but stores are subject to expropriation by human enemies. One possible biological clue to the resolution of this problem is that signs of episodic stress (enamel hypoplasia and microdefects in teeth in skeletal populations) generally become more common after agriculture was adopted.

Sedentary agriculture seems likely to have increased human fertility through a variety of mechanisms, including the shifting work loads for women; calorically richer diets; sedentism; and the increased marginal utility of children or the increased availability of weaning foods. Some researchers estimate that during the Mesolithic-Neolithic transition in the Iberian Peninsula fertility may have increased as much as from four to six live births per

mother, which would imply very rapid acceleration of population growth. If, in fact, fertility on average increased (possibly significantly) but population growth on average accelerated only by the trivial amount calculated below, then life expectancy must on average have declined (since growth rates are a balance of both fertility and mortality). (There is little evidence from paleopathology that the adoption of sedentary farming increased on average human life expectancy and little reason to expect that it did.)

For whatever reasons, essentially all estimates of average post-domestication population growth suggest an increase in rates of population growth (calculated as compound interest rates). But on average, the increase can have been no more than from about .003 percent per year for pre-Neolithic hunter-gatherers to about 0.1 percent for Neolithic and post-Neolithic farmers. (In both cases the averages are simple mathematical calculations of what is possible based on all reasonable estimates of world population at the period of adoption of agricultural (about 5–25 million) to estimated population in 1500 C.E. (about five hundred million). Average population growth even after the onset of agriculture would therefore have been trivial to the point where it would have been almost imperceptible to the populations involved. It would have taken such populations about one thousand years to double in size. Growth and dispersal of agricultural populations and/or diffusion of domestic crops were hardly likely to have been exuberant in most locations for that reason, particularly if arguments about declining health and very low average growth rates are considered. Owing to their low rank as resources, crops would presumably have diffused only to populations facing similar levels of demand or pressure but lacking good local domesticates of their own.

On the other hand, population growth might have been comparatively quite rapid in some areas because of increased fertility and improved life expectancy. Exuberant growth in some areas, such as Europe, must have been balanced by the decline of other populations, including those of other farmers. Exuberant growth, or diffusion, perhaps based on the relative quality of some cereals such as wheat and barley among otherwise low-ranking, intensively exploited resources, is observable in areas (such as the expansion of the Middle Eastern farming complex and probable expansion of agriculture populations into Europe). But even there, in contrast to old models assuming population expansion of hunter-gatherer “bands” into areas of very low population density, expansion would, based on observed intensity of exploitation, have been expanding into areas occupied by hunter-gatherers, who would by this time have had population densities and social complexity almost equal to their own. The pre-existing size and structure of groups of hunter-gatherers in areas of agricultural spread suggests that diffusion may have played a bigger role in the process than was once assumed.

Since health and nutrition seem to have declined, the primary advantage to farmers seems to have been both political and military because of the ability to concentrate population and raise larger armies. This would have conferred a considerable advantage in power at a time when few if any weapons were available that were capable of offsetting numerical superiority.

**AGRICULTURE SINCE THE INDUSTRIAL REVOLUTION.** It is difficult for people living in an advanced industrialized society to fully comprehend the life of a modern farmer, much less the life of farmers living before the Industrial Revolution. Up until the end of the eighteenth century, the vast majority of people were farmers who, as described by the English philosopher Thomas Hobbes in *Leviathan*, lived lives that were "solitary, poor, nasty, brutish and short." And so it had been since the beginning of time for the vast majority of people, until the advent of an agricultural revolution that started in Great Britain during the early 1700s, reached North America by the mid-1800s, and continues to this day in all but the most benighted of nations. Agriculture

had been changing since it had first appeared thousands of years earlier, but the pace quickened during the start of the Industrial Revolution in the eighteenth century, and changes that had previously taken centuries and generations began to occur within decades. By 1750, the best English agriculture was the best in the world. The most technologically advanced agriculture, it was also fully integrated into a market economy. The dominance of the British Empire in world affairs during the eighteenth and nineteenth centuries ensured that these agricultural improvements were widely distributed.

The Europe-centered Industrial Revolution of the eighteenth and nineteenth centuries accelerated an ongoing revolution in agriculture. In the industrialized West, animal power and human labor were first augmented and then almost completely replaced with mechanized sources of power. This was only part of the changes that gathered momentum in the 1700s and then transformed the world. Spectacular developments in all areas of science and nearly two centuries of exploration and conquest in the New World caused many Europeans in the early nineteenth century to reevaluate their relationship with nature. They developed an expanded worldview; it appeared to them that humanity in general, and Europeans specifically, had acquired the wisdom, knowledge, and scientific technology to dominate nature. This conviction was reinforced by the publication in 1859 of the *Origin of Species* by Charles Darwin. While the new attitude initially produced colonialism, rampant environmental pollution, and the exploitation of poorly organized workers, it also permitted the manipulation of the entire farming environment to an extent inconceivable to previous generations, and later produced for common people a standard of living previously available only to the aristocracy.

This new point of view stripped plants, animals, and soil of their mystical "vital" attributes and made of them machines to be molded to fit human needs. Physics, chemistry, and biology became tools to dissect, examine, and then reconstruct agricultural systems to make them better than any that had previously existed on earth. This process started with improved methods of crop production, advances in livestock breeding, and the invention of new farm equipment during the latter part of the Industrial Revolution. Soil, for example, ceased to contain a vital essence that must be periodically replenished by removing it from cultivation (fallowing), and became an aggregation of mineral and organic structures and chemicals whose fertility could be maintained by the application of scientific management—crop rotation, fertilizers, irrigation, pesticides, and other new methods. Adoption of new power sources, such as steam, and increased use of chemicals followed. Today, improved plant and livestock breeding through genetic engineering promises to continue the revolution well into the future.

Agricultural advances after the Industrial Revolution greatly increased food production, but increased urban-

ization required food to be transported long distances from producers to consumers. As with the citizens of ancient Rome, inhabitants of the ever-expanding cities became increasingly dependent on the transport, preservation, and storage of food. People starved in one part of the world, while abundant harvests spilled from granaries in another. The storage and distribution of food, rather than its production, became crucial to millions of people.

There have been periodic learned pronouncements of impending mass starvation since the English economist Thomas Malthus first proposed in his 1798 *Essay on the Principle of Population* that food production could only increase arithmetically, while population would increase geometrically. Malthus wrote that population would exceed food production at some point, and an apocalypse would ensue. While population growth has borne out his thesis for the past two hundred years, a number of scientific advances have allowed agricultural production to keep pace with it. A few major and thousands of minor refinements in agricultural practices have steadily improved productivity.

### Farming Efficiency

Before the 1700s, the problem of soil fertility had been met by letting half or a third of the land go fallow for a year in two- and three-field rotations. A new four-field rotation was now based on growing specific kinds of crops in a sequence that took from or added to the soil different nutrients. Part of the field did not have to be left fallow, and the continuous use of the land greatly increased the production of forage crops used to support livestock through the winter, thereby vastly increasing the availability of meat and dairy products. The diet of even the poorest improved as they could now afford to augment their daily bread with meat and cheese.

Another major change was a rapid acceleration in the fencing of large tracts of land to produce more efficient units of production. The enclosure movement in England did away with many traditional smallholdings, combining the land into larger tracts that could be more efficiently farmed. Earlier subdividing of land among generations of sons had produced a patchwork-quilt distribution of fields. A farmer may have had access to sufficient crop area (around twenty acres) to support his family, but it would be in small strips scattered among the holdings of other farmers, in a number of fields. This was because it was thought that each field had to remain fallow for a year to recover its fertility. From 1750 to 1831, enclosures consolidated these smallholdings into fields whose size could benefit from the application of modern methods of crop production.

Until the 1700s and 1800s peasants in most European countries could not actually own the land they farmed, but held ancestral rights to work land belonging to the proprietors of large estates. When laws were passed that allowed British landowners to abrogate these traditional agreements and combine many smallholdings,

thousands of farm families were displaced. Migrating to urban areas, they furnished the labor that fueled the Industrial Revolution, and the wretched characters who populated many of Charles Dickens's novels.

Throughout Europe, similar changes produced millions of restless people with a deep-seated desire to own land. Many emigrated to North America, Australia, and New Zealand, where a variety of homestead laws granted land to those who settled and worked a farm or ranch for a number of years. Based on these policies, the family farm became an institution in North America during the nineteenth and twentieth centuries, and a social and political force that continues to shape our national character. A combination of economic and demographic changes, however, has led to the steady decline in the number of functioning family farms. Although the U.S. population doubled between 1930 and 2000, the number of farms fell from 7 to 2 million. After 1987, this decline stabilized at about one percent annually. The price farmers got for commodities such as corn and soybeans remained virtually constant between 1970 and 2000, while the price they paid for everything they bought kept pace with inflation. This produced a farming population 60 percent of whom had farm incomes below the poverty line. It also discouraged the young so much that the number of farmers under the age of twenty-five decreased 50 percent between 1990 and 2000.

The large capital inputs needed to start and run a farm have transformed the production of many agricultural crops into large businesses. Ninety percent of U.S. farms, however, continue to be classified as individual operations, accounting for 71 percent of farmland and 74 percent of gross farm sales. Partnerships and corporations comprise a very small share of American farms, and people related by blood or marriage own 90 percent of them. Average acreage is higher for corporate farms (1,165 acres) and for partnerships (856 acres) than for individual operations (373 acres). Whereas the United States in the year 2000 had 2 million farms, just 60,000 of them produced 75 percent of the nation's farm output. Fewer and fewer farms were thus producing more and more of what Americans ate. The 1.3 million farms with incomes below \$20,000 comprised 60 percent of the total number of farms, but cultivated only 17 percent of the total U.S. farm acreage. In contrast, the 60,000 farms with sales over \$250,000 comprised only 7 percent of the total number, yet cultivated almost 30 percent of the acreage.

The many improvements in crop production up to 1935 produced only modest increases in average yield per acre in America because of deteriorating soil fertility and poor water use. Control of erosion, soil conservation, extensive government-backed irrigation developments, and better water-use efficiency reversed this trend, leading to large increases in production.

Since 1950, the gap in efficiency between the most productive mechanized agricultural systems and the least

productive manual farming systems has increased twentyfold. While in small part the result of reduced soil, water, and environmental quality in developing countries, this change really reflects the spectacular advances in agricultural technology in industrialized countries. Transference of this technology to farmers throughout the world should be a major goal, and will be a major challenge to the fortunate few in the coming decades.

### **Livestock Breeding**

Before the eighteenth century, raising animals was slow and costly; thus, meat and dairy products were usually scarce and expensive before the Industrial Revolution. The lack of sufficient forage to keep large numbers of animals over the winter often led to the slaughter of most livestock in the fall. Celebrants at many late fall festivals not only consumed the bountiful harvest of the field, but also the animals whose progeny could have supplied them with fresh meat, milk, and cheese the following year. Each spring, herds had to be rebuilt from the survivors.

Farmers had used their intuition and observations to breed animals for millennia, but the process was slow and haphazard because the inheritance of desirable traits was poorly understood. In the late 1700s Robert Bakewell, an English farmer, showed how intensive breeding for desirable traits could produce improved cattle, horses, and sheep. In Europe, sheep had been raised mainly for wool because they fattened too slowly to provide an economic source of meat. Bakewell's Leicester breed fattened quickly and could therefore be raised for both wool and slaughter. The cost of mutton dropped so low that it became the most popular meat in England, Australia, and New Zealand.

Breeding of livestock is now a science in industrial societies, with genetic analysis an integral aspect. Accurate monitoring to detect estrus, or its induction by hormones, and the use of artificial insemination allow complete control over the reproductive cycle of most livestock. Removal of ova, their *in vitro* fertilization, and embryo implantation promise to allow a further level of control and manipulation of the reproductive process. For example, separation of the cells resulting from the first divisions of the fertilized ovum (zygote) may be used to produce a number of embryos that, when implanted, give rise to whole herds of genetically identical animals. These techniques are being coupled with the genetic engineering of DNA in specific chromosomes, or the replacement of the entire nucleus in a zygote with a nucleus from another individual of the same, or a related, species (cloning). While possibly replete with ethical conundrums, these procedures will surely transform livestock into units of production whose fecundity, efficiency, and vigor would marvel our ancestors.

### **Plant Breeding**

Once Mendelian genetics was rediscovered in 1900, science gave plant and animal breeders a clear under-

standing of how traits were controlled by genes on chromosomes, and how they could be altered by selective breeding. Breeders made full use of this knowledge to steadily improve livestock and crops. Plants such as maize, soybeans, tomatoes, and peanuts became dietary staples in many parts of the world after their introduction from the Americas, Africa, and Asia. Identifying the sites of their origin helped locate ancestral forms of many crops, and these plants provided additional genetic resources to improve commercial varieties.

The upper limit of plant productivity is imposed by the quantum efficiency of photosynthesis and the energy content of sunlight. The photosynthate translocated from leaves not only produces the harvestable commodity, but is also used for all other plant functions. Reducing the drain of these other functions can increase yield. For example, symbiotic microorganisms in nodules on soybean roots can fix atmospheric nitrogen. It is often cheaper, however, to supply nitrogen fertilizers fixed by processes involving fossil fuels than to incur the loss of yield that would result from the soybean plant fixing a similar amount of nitrogen. Modification of the basic biochemistry and physiology underlying crop and livestock production will require levels of scientific knowledge and technical sophistication currently unavailable.

Economics of industrial-scale production require that most agriculture is monoculture, involving vast fields and herds of nearly genetically identical crops and livestock. This uniformity simplifies all aspects of production, but it also invites epidemics of plant disease. The devastating outbreak of bacterial southern corn blight in the United States in 1970, and the 2001 epidemic of viral foot-and-mouth disease in England, are examples of the seriousness of this problem. A major goal of plant and animal breeders is to stay ahead of chronic or exotic pathogens that can decimate crops and herds.

Genetic engineering has the potential to quickly create crops and livestock with unique characteristics. Rapid release of genetically modified organisms is slowed, however, because they require the same extensive field testing as new strains derived from traditional breeding. Consumer wariness has slowed the introduction of GMOs in Europe, but American consumers have readily accepted them. Most U.S. consumers have been unaware of the presence of GMOs in their food, and when they become aware, they are willing to accept claims by scientific and government sources that GMOs are safe to eat and environmentally benign. In Europe, a greater level of environmental activism and skepticism in government and scientific pronouncements has contributed to consumers' doubts about the safety and environmental impact of GMO crops. A large percentage of U.S. corn, soybean, and cotton production uses GMOs that possess pest resistance. Tailoring GMOs to the specific needs of farmers in developing countries may be the only way for food production to keep pace with their rapidly increasing populations. Crops designed with increased

disease and drought resistance and better use of nutrients in the soil could supplant the strains that have been developed for use in industrialized countries and that require expensive irrigation, pesticides, and fertilizers that are unavailable in developing countries.

Development of hybrid corn was a watershed in plant breeding, heralding a change in concept from a straightforward selection of desirable characteristics to the employment of a deeper understanding of the genetics involved. Experiments by G. H. Shull in 1906 showed that crossing could reverse reductions in vigor resulting from inbreeding. Using the strategy of double-cross hybrids suggested by D. F. Jones in 1918, the first commercial corn hybrid was released in 1921. About 95 percent of the corn now grown is hybrid, and use of double-cross hybrids allows 20 percent more corn to be produced on 25 percent fewer acres than when hybrid corn first became widely available in 1930. Hybrids of many other agronomic and horticultural crops have since been developed.

**The Green Revolution.** The Green Revolution, a sterling example of how the development of strains suited for developing countries, and a multifaceted approach to agriculture, can greatly increase food production, was a planned international effort funded by the Rockefeller and Ford Foundations and the governments of many developing countries. In the early 1950s, wheat production in Mexico had encountered an insurmountable yield barrier because the varieties being grown became too tall, top-heavy, and lodged (fell over and were difficult to harvest) when heavily fertilized. Using short-stalked lines developed years earlier by the U.S. Department of Agriculture, Norman E. Borlaug led an effort to develop broadly adapted, short-stemmed, disease-resistant wheats that excelled at converting fertilizer and water into high yields. Mexico went from importing half its wheat in 1964 to exporting half a million tons annually within two decades.

The Green Revolution is an agricultural success story. It increased food production in Mexico tenfold from 1960 to 1990 through the use of new crop varieties, irrigation, fertilizers, pesticides, and mechanization. At the same time, famine decreased 20 percent, caloric consumption per capita increased 25 percent, and incomes and standards of living increased. The successes in Mexico led to the establishment of a rice-breeding center in the Philippines. Working at about eighteen such centers worldwide, plant breeders have produced high-yielding varieties of virtually every major crop, including potato, sorghum, maize, cassava, and beans. Increased population growth and poor husbandry of natural resources, however, have eroded many of these gains since the 1980s.

### Farm Equipment

Preparing the soil with a plow, planting seeds, cultivation, harvesting, and threshing are some of the most important steps in crop production, and some of the most

labor- and energy-intensive. Inventions in the eighteenth and nineteenth centuries transferred much of farm labor to machines. Before Jethro Tull invented the precision seed drill in 1701, seeds were inefficiently planted by scattering them over a prepared field. Stands were thus often erratic and almost impossible to cultivate. The uniform placement of seeds in straight rows allowed horse-drawn cultivators to move easily up and down the rows for the control of weeds.

Little cotton was grown in the United States before the late 1790s because of the difficulty of separating the lint from the seed. Development of the cotton gin by Eli Whitney in 1793 greatly reduced the cost of producing cotton fiber for the rapidly increasing British textile industry. Slumps in production of tobacco, indigo, and rice during the 1790s had undermined the economic justification for slavery, but increased production of sugarcane and upland cotton still relied on the institution. The production of cotton in America now jumped twentyfold, from 2 million pounds in 1790 to 40 million pounds in 1800, while exports increased over 1000 percent in the same period. In less than a generation, cotton became the major crop grown in the U.S. South, and it revived the moribund slave-worked plantation system.

The first successful harvester or reaper was invented by Cyrus McCormick in 1834, as was the first modern thresher, by Hiram and John Pitts. The outbreak of the American Civil War in 1861 and subsequent conscription depleted farm labor, and forced many wheat farmers to buy reaping machines. The harvesting and threshing functions were later integrated into one machine, the combine, which did not become widely used until the early 1900s. Replacement of the cast-iron plow by the self-polishing steel plow, invented by John Deere in 1837, reduced the energy needed to plow a field because soil did not adhere to the smooth surface. To reach their full potential, most of these inventions depended on mechanical sources of power, which did not become readily available until the early twentieth century.

The major functions of a machine were often perfected over years of experimentation and modification. Sometimes mechanical limitations prevented further refinements, or an existing machine could not be easily modified to accommodate a new crop. When that occurred, it might be found easier to modify the crop to fit existing machines than to build entirely new machines. Dwarf sorghum was developed so it could be harvested with only slight modifications to an existing combine, and soybeans were developed that bore pods higher on the stalk so they could more easily be harvested. Tomatoes for processing were developed that had a more uniform set and were tough enough for mechanical harvesting using existing technology.

Integration of computers, sensors, and global positioning satellites into field equipment promises to revolutionize the planting, cultivation, and harvesting of many crops. For example, the location of each corn or tomato

plant in a field can be identified using sensors and GPSs, and stored in computer memory. Subsequent operations such as weeding, applications of pesticides and fertilizers, and harvesting can then be positioned to maximize the effectiveness of every operation, thereby increasing yield and quality while at the same time reducing expenditures of time, fuel, and chemicals.

### Energy and Information

In essence, farming is the conversion of sunlight and other sources of energy into food. For most of recorded history the energy to plant, cultivate, harvest, and process crops was supplied by the farmer and by domesticated draft animals (such as oxen and horses). Necessarily, the energy captured by the plant and harvested as food calories had to exceed that expended in its production. Preindustrial agriculture generally returned around twenty times more calories in the food consumed than was expended during its production. This efficiency decreases as the consumed food product requires additional processing (as for white bread versus grain potage, or cheese versus milk), conversion to other forms (cornflakes versus corn used to produce beefsteak), and shipment to distant consumers. As agriculture became mechanized, greater and greater amounts of energy were expended for each unit of food produced. Currently, mechanized agriculture in developed countries uses ten times as much energy to produce food as is returned in the food consumed. But agricultural mechanization has increased productivity so much that today's farmer can feed almost 150 people, while at the beginning of the twentieth century a farmer could feed only 2.5 people. The vast input of fossil fuels to synthesize the required fertilizers and pesticides, and to power the machinery that cultivates the fields, harvests the crops, processes them, and transports them to the consumer has so increased production that a small percentage of the population can raise enough food to keep most Americans overweight.

Before the Industrial Revolution, there was localized use of wind and water power for milling grain and pumping water, but these sources were stationary, and of no use in planting or plowing a field, or harvesting a crop. The earliest tractors were basically large stationary engines equipped with a drive system. At first, steam engines were immobile and of little use for field operations because of their enormous weight. Even in the mid-1800s steam-powered tractors were so expensive and difficult to operate that most farmers continued to use horses and mules to power farm machines. The introduction of high-pressure boilers in the 1850s lightened engines, and steam tractors enjoyed significant usage between 1885 and 1914. Tractors with internal-combustion engines eventually supplanted steam tractors because they had several advantages: they were cheaper, easier to operate, and less prone to explosions and fires.

World War I (1914–1918) did for the tractor what the American Civil War had done for the reaping ma-

chine. Soon after it began, German U-boats were sinking so many British ships that it was necessary to increase food production by bringing thousands of acres of new farmland into production or face food shortages. There were not enough horses to plow this new land, and only five hundred tractors in all of Britain. The five thousand tractors ordered by the British government from Henry Ford were delivered within five months, and were soon at work on British farms. Almost overnight, British farmers, and later their conscripted American visitors, became accustomed to seeing tractors displacing teams of horses.

The labor shortage and guaranteed market for crops during World War I stimulated U.S. tractor design and manufacture; massive industrialization led to greatly increased production. It was not until after World War II, however, that tractors became widely accepted. Many farmers bought early tractors, particularly the smaller, lighter machines that could do varied field work, but the worldwide depression of the 1930s and the fact that tractors still couldn't compete with the agility of horses in the field led to the demise of many tractor companies. Most farmers would have been thrilled to be rid of draft animals and to use mechanical devices. During the period 1908–1927 Ford built over 15 million automobiles with the Model T engine. Many farmers had a car or truck that was used to supply power for nonfield operations and for trips to town, yet continued to use draft animals for fieldwork; the Sears catalog of the time listed hundreds of accessories that could be used with the drive train of a car or truck to do everything from threshing grain and pumping water to churning butter, sawing wood, and washing clothes. Only when tractors appeared with enough power and maneuverability for fieldwork and the flexibility to furnish power for other nonfield operations were they readily adopted by most farmers. It was not until the 1920s that the all-purpose tractor made its appearance and gradually replaced steam-powered machines and draft animals. By the 1930s, seven tractor companies controlled over 90 percent of the market, and North America led the world in tractor design and production. Today, tractors using gasoline or diesel engines are ubiquitous on farms throughout the world.

Most farms in Europe and Japan had electrical power by the mid-1930s. Only 10 percent of U.S. farms were so supplied, however, at the time the Federal government established the Rural Electrification Administration in 1935. The REA supplied economic incentives that stimulated rural electrification; by 1960, over 97 percent of American farms had electricity.

Electricity brought with it better communication through the telegraph, telephone, radio, television, and eventually the Internet, all of which in turn have had tremendous effects on the farmer's life. Farms are no longer isolated from the mainstream of society. Information on weather and on commodity prices is readily available, and can assist in better planning. Farming has become such a capital-, energy-, and information-

intensive business that most farmers need assistance in managing it all. Most industrialized countries have government-sponsored agricultural-research and extension services. These not only engage in practical research of immediate and local importance, but also provide significant levels of basic research to address future problems. They assist farmers, marketers, and distributors through publications, interactive websites, classes, and farm visits and demonstrations. Almost more than any other aspect of modern agriculture, the extension services are responsible for today's unmatched levels of food production, nutrition, and safety.

### Agricultural Chemicals

All living things are groups of simple and complex chemicals functioning together in specific and unimaginably complex ways. Since all living things are interrelated through evolution, they are very similar at the molecular level. This means that many require roughly the same resources (thus, all plants need sunlight, carbon dioxide, water, and a few common minerals), and can be food for one another (thus, the starch stored by a potato can be used for its future growth or consumed by humans). Many organisms therefore compete for the same scarce resources and develop elaborate strategies to avoid being eaten. Weeds are simply plants that out-compete crops for the resources that limit plant growth and that we apply in profusion to cultivated crops. During domestication, the elimination of many natural defense mechanisms to produce a more easily grown, harvested, or palatable crop also produces a crop more vulnerable to pests. Reintroduction of specific natural defense mechanisms through selective genetic engineering could drastically reduce the dependence of agriculture on synthetic pesticides.

Modern agriculture is based on the establishment of a monoculture in which one specific crop or animal is grown or raised over large areas to the exclusion of all potentially competing organisms. Methods of planting, cultivation, and harvesting are all geared to the growth of uniform plants and animals. An orchard is usually composed of genetically identical (cloned) trees. Each tree will flower at roughly the same time, and produce fruits that look and taste the same and ripen at the same time. Fields are often modified to provide growing conditions that are as close as possible to being identical for all plants to further limit variability. Pruning, applications of pesticide sprays, cultivations, irrigation, and harvesting can be done over the entire orchard because all trees and fruit are at similar stages of growth and will respond similarly. An orchard composed of dissimilar seedlings would have trees that flowered at different times, and have fruit that were green or red, sweet or tart, or large or small, and that ripened at different times. The susceptibility of trees and fruits to various pests would be different, so different pesticides would have to be used at different times and rates of application. As with the other field operations, harvesting would have to be done a number of

Wheat harvest on a collective farm near Lvov, Ukraine, in 1991. © PETER TURNLEY/CORBIS.

times, and would have to be selective since the fruit on each tree would ripen at a different rate. Fruit, or any other agricultural commodity, produced in this way would be expensive and of variable quality—two attributes abhorrent to modern consumers.

Most undisturbed natural ecosystems are stable because they contain many species of plants and animals that are genetically diverse, that can exploit all the available niches, and that interact with one another to hinder the uncontrolled growth of a single pest or disease. In a monoculture the genetic and species diversity that provides stability is lacking, and control must be exerted by the farmer to maintain the health of the crops or animals and ensure an ample, high-quality yield.

Agricultural chemistry had become a recognized discipline by the mid-nineteenth century. Fertilizers and other products of the chemical industry became widely used early in the twentieth century, and have become indispensable in maintaining the yields of modern agriculture. Reliance on chemical answers to agricultural problems, however, has often obscured their deficiencies, as well as the existence of alternative solutions. Crop rotation and cultural practices have long been used to control pests. Since the end of World War II, however, farmers and ranchers have come to rely more heavily on chemical pesticides (such as insecticides, herbicides, fungicides, and nematocides). Shortly after DDT was found to be an effective insecticide in 1939, the United States began producing large quantities of it to control vector-borne diseases such as typhus and malaria. The dramatic success of DDT in controlling over five hundred insect pests diverted attention from traditional nonchemical methods of pest control. The publication of *Silent Spring* by Rachel Carson in 1962, however, made the public aware of the environmental drawbacks of using too many

pesticides. Since then, there has been a complete shift in research emphasis, so that, whereas in 1925 three-fourths of published studies were on chemical pesticides, almost 80 percent of USDA pesticide research in 2000 was on alternatives to chemicals.

Environmental concerns, regulatory legislation, and increased costs were driving forces in the development of Integrated Pest Management (IPM) programs throughout the United States in the early 1970s. Bringing together experts from many fields, IPM programs strive to reduce the usage of chemical pesticides by integrating knowledge about the biology of the pest, the response of the crop to infestation, and the costs involved in applying or withholding treatment. Researchers have recognized that the pest population does not have to be completely eliminated, only kept below the point at which the farmer starts to lose money because of it. Implementation of these types of programs has significantly reduced the use of chemical pesticides while maintaining yield, quality, and economic return.

Fertilizers represent the single largest use of chemicals on the farm. Although nitrogen gas comprises 80 percent of the air we breathe, it is the element most commonly limiting plant growth. Atmospheric nitrogen must be fixed into ammonia or nitrates before a plant can use it. Lightning and biological activity (such as that of symbiotic microorganisms in nodules on legume roots) can fix nitrogen. The vast majority of nitrogen used in fertilizer, however, is fixed by the Haber process, an elegant method of combining nitrogen from air with hydrogen from natural gas under high pressure and temperature to produce ammonia. This process was invented by German scientists before World War I in response to a blockade of Chilean nitrate imposed by the British Royal Navy. During the war it was used to fix nitrogen for agriculture and to produce explosives. The inorganic ammonia fixed by this process now supplies about the same amount of nitrogen for crops as is fixed by all natural organic processes. The synthesis of ammonia consumes about 2 percent of the fossil fuel used worldwide. Overuse of cheap nitrogen fertilizer can lead to excessive runoff that pollutes groundwater and to eutrophication of bodies of water. But while inorganic nitrogen fertilizers remain cheap, it will cost less to apply them to crops than to have the plant divert its photosynthate from producing a crop to fixing its own nitrogen.

**AGRONOMY.** Agronomy embraces the branch of agriculture that deals with the development and practical management of plants and soils to produce food, feed, and fiber crops in a manner that preserves or improves the environment. The term "agronomy" represents the disciplines of soils, crops, and related sciences. In the soils area, specialties include soil microbiology, soil conservation, soil physics, soil fertility and plant nutrition, chemistry, biochemistry, and mineralogy. Specialties in the crops area relate primarily to plant genetics and breeding, crop physiology and management, crop ecology, turf-grass management, and seed production and physiology. Researchers in agronomy often work in close cooperation with scientists from disciplines such as entomology, pathology, chemistry, and engineering in order to improve productivity and reduce environmental problems. Even though less than 2 percent of the U.S. population are farmers who actively produce farm crops, the need for agronomists by other segments of society is increasing.

In the United States, field crops consist of those plants grown on an extensive scale, which differs from horticultural crops, which are usually grown intensively in orchards, gardens, and nurseries, but the distinctions are disappearing. Some of the major agronomic crops grown in the United States are alfalfa and pasture crops, peanuts, corn, soybeans, wheat, cotton, sorghum, oats, barley, and rice. Soil management aspects of agronomy encompass soil fertility, land use, environmental preservation, and non-production uses of soil resources for building, waste disposal, and recreation. Agronomists who work as soil scientists play extremely important roles

The basic idea behind agronomy is to match crops to their environment. This means following the contours of the land as well as choosing crops best suited for maintaining soil productivity. COURTESY OF THE JOHN DEERE LIBRARY.

in helping preserve water quality and preserve natural environments.

Agronomy is not a new field. As early as 7000 B.C.E. wheat and barley were grown at Jarmo, in present-day Iran. One could argue that the first farmers were in fact agronomists. In prehistoric times, humans shifted from foraging to cultivating specific crops, probably wheat or barley, for their food value. At harvest time, plants with easily gathered grain were selected first. This natural selection eventually made these food plants better adapted to continued cultivation because they were more easily harvested. Throughout the centuries, selection also occurred for other crop characteristics, such as taste, yield, and adaptation to specific soils and climates. The goal of today's production agronomists is essentially the same: to improve the quality, adaptability, and yield of our most important crops.

### The Science of Agronomy

There are both basic and applied aspects of agronomy. Agronomists examine very basic components of soils and crops at subcellular or molecular levels. For example, at the basic level, agronomists use sophisticated techniques to unravel the genetic makeup of major crops in order to change their adaptation, nutritive value, or to breed medicinal benefits into agronomic crops. Genetic improve-

ment is an area where major breakthroughs are likely to occur. Agronomists have developed highly specialized computer models of crop growth in order to better understand how environmental and management components affect the way crops grow. These models help in the development of such things as precision fertilizer application techniques, which provide the crop with the correct amount of nutrients at the correct time in its life cycle. This technique helps reduce fertilizer overapplication, which is costly to the farmer, and may increase groundwater pollution. Models of how chemicals move in the soil also help assure proper application of animal manures, municipal waste, and soil amendments necessary for crop growth. Molecular components of soil constituents are studied to determine basic interactions affecting plant growth and nutrition, and soil and water quality.

### Crop Production and Soil Management

Crop production consists of integrating all aspects of the field environment to assure an economically feasible and environmentally sound system of growing crops. At the applied level, agronomists use basic research information to help manage crop production systems and soil and water conservation programs. Agronomists provide a wealth of information to farmers to assure the soundness of their production programs.

Environmental and economic conditions vary dramatically, and crops must be adapted to the soils and climate for efficient crop production. Crops such as wheat grow best in the Great Plains of the United States, because wheat is well suited to the soils, rainfall, and length of growing season of the area. Likewise, crops such as cotton and peanuts are best adapted to the southern United States because these crops require warmer temperatures, a longer growing season, and more rainfall than does wheat.

Applications of sound principles of soil management are key to maintaining a healthy environment. Agronomists aid in identifying environmental risks and devise methods of reducing these risks. Management techniques developed by agronomists include terracing, strip cropping, and reduced tillage methods to reduce soil erosion. Developments in Global Information Systems (GIS) and site-specific technology are being used by agronomists to more precisely manage how, when, and where to apply soil amendments and fertilizers. GIS is also extremely useful in identifying type and extent of pest infestations. This helps reduce environmental pollution by pinpointing when and where to apply pest control and reducing the amount of pesticides used in crop production.

### International Agronomy

Agronomy is an international discipline. Many of the problems, issues, and challenges faced by societies around the world are universal in nature, and require international cooperation. For example, a major problem facing the developed world is that of how best to use our land resources. Within the developing world, the same problems exist. The questions of how much and which land should be saved for food and fiber production and which land should be used for nonagricultural uses must be addressed by both developing and developed societies. Agronomists play a crucial role in assessing land quality to assure an environmentally friendly use of land. Studying how plants adapt to differing climates and environments has allowed plant scientists to increase food and fiber production in regions of the world where the necessities of life are most limited. Knowledge gained and disseminated by agronomists in the developed world has helped improve the human condition in the developing world. For example, plant geneticists and breeders use similar hybrid and variety development techniques in both developed and developing countries. Through plant breeding, for example, agronomists have developed high-yielding rice that is adapted to tropical climates. Breakthroughs in gene transfer permit plant breeders to improve grain quality and nutritional traits. These techniques have also contributed to increased production efficiency by genetically incorporating into food crops increased pest resistance and by broadening their range of adaptation.

**ALCOHOL.** The word "alcohol" is derived from the Arabic word *al kuhul*, meaning 'essence'. The favorite mood-altering drug in the United States, as in almost every human society, continues to be alcohol. One of the reasons for the significant use of alcohol and its health impact is its feature of being (along with nicotine) a legally available drug of abuse and dependence.

Our knowledge of alcohol rests on a heritage of myth and speculation. Many health benefits have been attributed to alcohol by ancient healers who saw ethanol as the elixir of life, but almost none of its positive benefits have stood the test of time. Alcoholic beverages have been revered, more than any other substance, as mystical and medicinal agents. In recent years, however, we have stripped away much of the mystery surrounding alcohol and now recognize it as a drug with distinct pharmacological effects. However, one of the reasons that beverages containing alcohol continue to be consumed is related to the folklore and history that surround its many combinations with other flavors and its many sources of fermentation and distillation.

### Chemist's View

Today one thinks of alcohol and alcoholic spirits as being synonymous, yet to a chemist an alcohol is any of an entire class of organic compounds containing a hydroxyl (OH) group or groups. The first member of its class, methyl alcohol or methanol, is used commercially as a solvent. Isopropyl alcohol, also known as rubbing alcohol, serves as a drying agent and disinfectant. Ethyl alcohol or ethanol shares these functions but differs from other alcohols in also being suitable as a beverage ingredient and intoxicant. Ethanol also differs from other alcohols in being a palatable source of energy and euphoria. It is a small, un-ionized molecule that is completely miscible with water and also somewhat fat-soluble. The remainder of this article pertains to ethanol, but refers to it simply as alcohol.

### Biology of Production

Making alcoholic beverages dates back at least eight thousand years; for example, beer was made from cereal

mashes in Mesopotamia in 6000 B.C.E. and wine in Egypt in 3700 B.C.E.

Ethyl alcohol is actually a by-product of yeast metabolism. Yeast is a fungus that feeds on carbohydrates. Yeasts are present ubiquitously. For example, the white waxy surface of a grape is almost entirely composed of yeast. When, for example, the skin of a berry is broken, the yeast acts quickly and releases an enzyme that, under anaerobic conditions, converts the sugar (sucrose,  $C_{12}H_{22}O_{11}$ ) in the berry into carbon dioxide ( $CO_2$ ) and alcohol ( $C_2H_5OH$ ). This process is known as fermentation (if the mixture is not protected from air, alcohol turns into acetic acid, producing vinegar). When cereal grains and potatoes are used, each requires a sprouting pretreatment (malting) to hydrolyze starch, during which diastase enzymes are produced that break down starches to simple sugars that the yeast, which lacks these enzymes, can anaerobically convert to alcohol. This process makes the sugar available for the fermentation process. The yeast then continues to feed on the sugar until it literally dies of acute alcohol intoxication.

Because yeast expires when the alcohol concentration reaches 12 to 15 percent, natural fermentation stops at this point. In beer, which is made of barley, rice, corn, and other cereals, the fermentation process is artificially halted somewhere between 3 and 6 percent alcohol. Table wine contains between 10 and 14 percent alcohol, the limit of yeast's alcohol tolerance. This amount is insufficient for complete preservation, and thus a mild pasteurization is applied.

Distillation, which was discovered about 800 C.E. in Arabia, is the man-made process designed to take over where the vulnerable yeast fungus leaves off. The distilled, or hard, liquors, including brandy, gin, whiskey, scotch, bourbon, rum, and vodka, contain between 40 and 75 percent pure alcohol. Dry wines result when nearly all the available sugar is fermented. Sweet wines still have unfermented sugar. Pure alcohol also is added to fortify wines such as port and sherry. This addition boosts their percentage of alcohol to 18 or 20 percent (such wines do not require further pasteurization). "Still wines" are bottled after complete fermentation takes place. Sparkling wines are bottled before fermentation is complete so that the formed  $CO_2$  is retained. "White" wines are made only from the juice of the grapes; "reds" contain both the juice and pigments from skins.

The percentage of alcohol in distilled liquors commonly is expressed in degrees of "proof" rather than as a percentage of pure alcohol. This measure developed from the seventeenth-century English custom of "proving" an alcoholic drink was of sufficient strength. This was accomplished by mixing it with gunpowder and attempting to ignite it. If the drink contained 49 percent alcohol by weight (or 57 percent by volume), it could be ignited. Thus, proof is approximately double the percentage of pure alcohol (an 86 proof whiskey is 43 percent pure alcohol).

Pure alcohol is a colorless, somewhat volatile liquid with a harsh, burning taste, which is used widely as a fuel or as a solvent for various fats, oils, and resins. This simple and unpalatable chemical is made to look, taste, and smell appetizing by combining it with water and various substances called congeners (pharmacologically active molecules other than ethanol, including higher alcohols and benzene). Congeners make bourbon whiskey taste different from Scotch whiskey, distinguish one brand of beer from another, give wine its "nose" and sherry its golden glow. In trace amounts, most congeners are harmless, but their consumption has been linked to the severity of hangovers and other central nervous system symptoms that include sleepiness.

### Use in Food Products

Wines, liqueurs, and distilled spirits are used to prepare main dishes, sauces, and desserts, creating new and interesting flavors. The presence of alcohol in significant amounts affects the energy value of a food. Alcohol is rich in energy (29 kJ/g, or 7.1 kcal/g). It is assumed that, because of its low boiling point, alcohol is evaporated from foods during cooking. However, almost 4 to 85 percent of alcohol can be retained in foods. Foods that require heating for prolonged periods (over two hours—for example, pot roast), retain about 4–6 percent; foods like sauces (where alcohol is typically added after the sauce has been brought to a boil) may retain as much as 85 percent.

### Alcohol and Malnutrition

Alcoholism is a major cause of malnutrition. The reasons are threefold. First, alcohol interferes with central mechanisms that regulate food intake and causes food intake decreases. Second, alcohol is rich in energy (7.1 kcal/g), and like pure sugar most alcoholic beverages are relatively empty of nutrients. Increasing amounts of alcohol ingested lead to the consumption of decreasing amounts of other foods, making the nutrient content of the diet inadequate, even if total energy intake is sufficient. Thus chronic alcohol abuse causes primary malnutrition by displacing other dietary nutrients. Third, gastrointestinal and liver complications associated with alcoholism also interfere with digestion, absorption, metabolism, and activation of nutrients, and thereby cause secondary malnutrition.

It is important to note that although ethanol is rich in energy, its chronic consumption does not produce the expected gain in body weight. This may be attributed, in part, to damaged mitochondria and the resulting poor coupling of oxidation of fat metabolically utilizable with energy production. The microsomal pathways that oxidize ethanol may be partially responsible. These pathways produce heat rather than adenosine triphosphate (ATP) and thereby fail to couple ethanol oxidation to useful energy-rich intermediates such as ATP. Thus, perhaps because of these energy considerations, alcoholics

Diagrams of alcohol-distilling equipment from Ambrose Cooper's *Complete Distiller* (London, 1760). Copper engraving. ROUGHWOOD COLLECTION.

with higher total caloric intake do not experience expected weight gain despite physical activity levels similar to those of the non-alcohol-consuming overweight population.

### Absorption and Metabolism

Unlike foods, which require time for digestion, alcohol needs no digestion and is absorbed quickly. The presence of food in the stomach delays emptying, slowing absorption that occurs mainly in the upper small intestine.

Only 2 to 10 percent of absorbed ethanol is eliminated through the kidneys and lungs; the rest is metabolized, principally in the liver. A small amount of ethanol also is metabolized by gastric alcohol dehydrogenase (ADH) [first-pass metabolism (FPM)]. This FPM explains why, for any given dose of ethanol, blood levels are usually higher after an intravenous dose than following a similar amount taken orally. FPM is partly lost in the alcoholic. This lost function is due to decreased gastric ADH activity. Premenopausal women also have less of this gastric enzyme than do men. This difference partially explains why women become more intoxicated than men when each consume similar amounts of alcohol.

Hepatocytes are the primary cells that oxidize alcohol at significant rates. This hepatic specificity for ethanol oxidation, coupled with ethanol's high energy content and the lack of effective feedback control of alcohol hepatic

metabolism, results in the displacement of up to 90 percent of the liver's normal metabolic substrates.

**Oxidation.** Hepatocytes contain three main pathways for ethanol metabolism. Each pathway is localized to a different subcellular compartment: (1) the alcohol dehydrogenase (ADH) pathway (soluble fraction of the cell); (2) the microsomal ethanol oxidizing system (MEOS) located in the endoplasmic reticulum; and (3) catalase located in the peroxisomes. Each of these pathways produces specific toxic and nontoxic metabolites. All three result in the production of acetaldehyde ( $\text{CH}_3\text{CHO}$ ), a highly toxic metabolite. The MEOS may account for up to 40 percent of ethanol oxidation. Normally, the role of catalase is small. It is not discussed further here.

1. *The ADH pathway.* The oxidation of ethanol by the ADH results in the production of acetaldehyde ( $\text{CH}_3\text{CHO}$ ) and the transformation of nicotinamide adenine dinucleotide (NAD) to nicotinamide adenine dinucleotide-reduced form (NADH). Substantial levels of acetaldehyde can result in skin flushing. Regeneration of NAD from NADH is the rate-limiting step in this ADH pathway of alcohol metabolism. It can metabolize approximately 13 to 14 grams of ethanol per hour (the amount in a typical drink). This rate is observed when blood alcohol concentrations reach 10 mg/dL. The large amounts of reducing equivalents that are generated by the alco-

hol oxidation overwhelm the hepatocyte's ability to maintain homeostasis and as a consequence a number of metabolic abnormalities ensue. Increased NADH, the primary form of reducing equivalents, promotes fatty acid synthesis, opposes lipid oxidation, and results in fat accumulation.

2. **MEOS.** This pathway also converts a portion of ethanol to acetaldehyde. Cytochrome P4502E1 (CYP2E1) is the responsible enzyme. As other microsomal oxidizing systems, this system also is inducible, that is, it increases in activity in the presence of large amounts of the target substrate. This induction contributes to the metabolic tolerance to ethanol that develops in alcoholics. This tolerance, however, should not be confused with protection against alcohol's toxic effects. It is important to note that, even though larger amounts of alcohol may be metabolized by individuals when this capability has been induced fully, most of alcohol's harmful effects remain unabated.

### Physiological Effects at Different Levels

**Beneficial effects.** A large variety of alcoholic beverages are available, and most people can find at least one that provides gustatory and other pleasures. Alcohol is said to reduce tension, fatigue, anxiety, and pressure and to increase feelings associated with relaxation. It also has been claimed that drinking in moderation may lower the risk of coronary heart disease (mainly among men over 45 and women over age 55), but whether that putative protection is due primarily to the alcohol or some other associated factors, such as lifestyle, remains controversial. Moderate alcohol consumption provides no health benefit for younger people, and in fact may increase risks to alcohol's ill effects because the potential for alcohol abuse increases when drinking starts at an early age.

**Harmful effects.** The problems of individuals who occasionally become drunk differ from those who experience drinking binges at regular intervals.

*"Acute" harmful effects of alcohol intoxication:* Occasional excess drinking can cause nausea, vomiting, and hangovers (especially in inexperienced drinkers). The acute neurological effects of alcohol intoxication are dose-related. These progress from euphoria, relief from anxiety, and removal of inhibitions to ataxia, impaired vision, judgment, reasoning, and muscle control. When alcohol intakes continue after the appearance of these signs and symptoms, progress to lethal levels occurs very quickly, resulting in the anesthetization of the brain's circulatory and respiratory centers.

*"Chronic" harmful effects of alcohol excess:* Chronic excessive alcohol consumption can affect adversely virtually all tissues. Alcoholics have a mortality and suicide rate 2½ times greater, and an accident rate 7 times greater

than average. Some of the dire consequences that are associated with alcohol abuse are:

1. **Cardiovascular problems.** Alcohol causes vasodilation of peripheral vessels (causing flushing), vasoconstriction (producing resistance to the flow of blood and increasing work load on the heart) and alcoholic cardiomyopathy (characterized by myocardial fiber hypertrophy, fibrosis, and congestive heart failure).
2. **Cancer.** Alcohol increases the risk of alimentary, respiratory tract, and breast cancers.
3. **Liver disease.** Alcohol can result in fatty liver, hepatitis, and cirrhosis.
4. **Central nervous system disorders.** Alcohol causes premature aging of the brain. Blackouts may occur (for example, those affected walk, talk, and act normally and appear to be aware of what is happening, yet later have no recollection of events experienced during the blackout).
5. **Gastrointestinal disorders.** Alcohol increases risk of esophageal varices, gastritis, and pancreatitis.
6. **Metabolic alterations.** Alcohol increases nutritional deficiencies (primary and secondary), and adversely affects absorption and utilization of vitamins. It impairs the intestinal absorption of B vitamins, notably thiamin, folate, and vitamin B<sub>12</sub>. Wernicke's encephalopathy also may occur. This condition is the result of severe thiamine deficiency. It is characterized by visual disorders, ataxia, confusion, and coma.
7. **Immunological disorders.** Alcohol decreases immunity to infections and impairs healing of injuries.
8. **Others.** Alcohol causes personality changes, sexual frigidity or impotency, sleep disturbances, and depression.

### Treatment

There are two major approaches that are used in the treatment of alcohol abuse: (1) correction of the medical, nutritional, and psychological problems; and (2) the alleviation of dependency on alcohol. Many sedatives or tranquilizers (for example, chlordiazepoxide) are effective in controlling minor withdrawal symptoms such as tremors. More serious symptoms include delirium tremens and seizures. For treatment of alcohol dependence, the anticraving agent naltrexone has shown promising results. Nutritional deficiency, such as lack of thiamine or magnesium, when present, must be corrected. Psychological approaches such as the twelve steps of Alcoholics Anonymous are also effective in achieving more sustained abstinence. These approaches, although helpful, too often come too late to revert the liver to its normal state. Other approaches, such as those focusing on prevention (utilizing biochemical markers), screening (through use of improved blood tests), and early detection are needed to impact on the prevalence of liver disease. The correction of nutritional deficiencies and

supplementation with other substrates that may be produced in abnormally low quantities by affected patients, for example, S-adenosylmethionine (SAME) and polyunsaturated lecithin have been shown to offset some of the adverse manifestations of alcohol's toxic effects. These and others are now being tested in humans.

## Conclusion

Alcoholism, an addiction to heavy and frequent alcohol consumption, is a major public health issue. However, many believe that this condition does not attract attention that it merits from either the public or the health professions. Alcoholism is a multifaceted problem that cannot be solved by any single approach. The "consumption control approach" is a worthwhile endeavor with proven efficacy, but consumption control efforts by themselves are not sufficient. Prevention of alcohol misuse before it occurs also can be beneficial. Another prevention strategy includes establishing standards and guidelines for advertising and emphasizing responsibility and moderation in the serving and consumption of alcohol. "Behavioral" approaches focus on recognition of social and psychological factors and their correction. Finally, the "disease-control" approach provides new insights. Continued research into the pathophysiology of alcohol-induced disorders increases understanding of the condition and provides prospects of earlier recognition, and improved efforts for its early prevention and treatment, prior to the medical and social disintegration of its victims. By combining all of these approaches, chances to alleviate the suffering of the alcoholic are multiplied in a positively synergistic manner and the public health impact of alcoholism on our society can be minimized.

**ALGAE, TOXIC.** Marine phytoplankton, or single-cell algae, are the base of the marine food chain. Phytoplankton use sunlight to convert simple inorganic

molecules, such as water and carbon dioxide, to complex organic compounds, such as protein, carbohydrates, and lipids. The ocean waters that surround continental coastlines are the home of a large number of marine algae, making them the most productive areas for the harvest of marine finfish and shellfish. Much of the time, algae are present at very low numbers, but when conditions are right, they can grow rapidly and explosively, producing a noticeable discoloration in the water called a "bloom." These blooms can cover very large areas of the coastal ocean that are often visible from satellites. Large numbers of "blooming" algae can, at times, produce toxins or result in lower oxygen levels in seawater, thereby creating significant problems for shore-based businesses (e.g., hotels, restaurants), the seafood industry, and consumers.

While many of these algal blooms are merely noxious (i.e., producing smelly odors, discolored water, gelatinous masses), some produce marine toxins that enter the marine food web when consumed by shellfish or finfish. Typically, these finfish and shellfish (particularly mussels) have a capacity to concentrate and accumulate very large amounts of these toxins without apparent harm to themselves. Toxin levels can be so high that consuming only a few mussels could be lethal. When blooms produce such deleterious effects, they are called harmful algal blooms, or HABs.

A variety of human intoxication syndromes have been characterized from the consumption of seafood contaminated with algal toxins. Five will be described here. For a detailed historical and descriptive treatment of the myriad seafood intoxications, please see the extensive monograph by Halstead, the chapter by Wekell and Liston, and *Seafood Safety* (pp. 87–110) in the bibliography. In the temperate zone, three HAB intoxications are of concern to seafood consumers and industry: paralytic shellfish poisoning (PSP), amnesiac shellfish poisoning (ASP, more correctly domoic acid poisoning), and diarrhetic shellfish poisoning (DSP). In semitropical and tropical waters, two syndromes have major impacts: neurotoxic shellfish poisoning (NSP) and ciguatera fish poisoning (CFP).

PSP and ASP present the greatest health risks due to the following factors: potency of the toxins, wide geographic distribution, and large coastal populations exposed to the toxins, thereby elevating the risk of human exposure to these toxins. In addition, shellfish production has increased to meet increasing worldwide demands. Perhaps the tropical poisonings (NSP and CFP) have disproportionately greater impacts because some of the "at-risk" populations in tropical communities are poor and dependent on seafoods for daily subsistence. In these regions, illnesses from these toxins have greater impact on daily lives than those in more developed and wealthier countries due to loss of work time and limited access to medical care. Since no antidotes are available, medical treatment for all seafood intoxications is limited to providing emergency measures (e.g., gastric lavage,

breathing assistance) and treating symptoms (Wekell and Liston, pp. 111–155).

### The Symptoms, Toxins, and the Organisms That Produce Them

**Paralytic shellfish poison (PSP).** Symptoms include paralysis of the peripheral muscles including the chest, making breathing difficult (in mild cases) to impossible in the most severe cases. Along the West Coast of North America, several deaths have been reported over the past decade from recreational and subsistence shellfish consumers. The only treatment is immediate medical intervention, that is, the use of artificial respiration until the toxins are purged from the victim's body. PSP is caused by the consumption of shellfish contaminated with a suite of toxins (about a dozen individual toxins have been identified). The first toxin to be chemically identified was named "saxitoxin" because it was found in the Alaskan butter clam (*Saxidomus giganteus*). Since then, other toxins have been identified and named "gonyautoxins," after the historical name (*Gonyaulax*) for the causative organism, currently known as the *Alexandrium* dinoflagellate. The PSP toxins and associated algae are found from the sub-Arctic (and sub-Antarctic) to tropical areas, but are most common in cooler temperate waters (both in the Northern and Southern Hemispheres). In the temperate zones, the toxins are produced by the dinoflagellates in the genus *Alexandrium*: specifically *A. catenella* and *A. tamarense*. In tropical and semi-tropical areas, the dinoflagellates *Pyrodinium bahamense* var. *compressum* and *Gymnodinium catenatum* have been implicated as producers of PSP toxins.

**Amnesiac shellfish poisoning (ASP or domoic acid poisoning).** The first identified outbreak occurred in 1987 in eastern Canada due to the consumption of mussels contaminated with domoic acid. Symptoms varied from mild gastroenteritis to the loss of short-term memory, and in the most severe cases, death. In this incident, the elderly appeared more susceptible than younger people. The toxin binds to parts of the brain responsible for memory and learning, resulting in nerve cell death. To date, in the United States, the most common vectors of lethal levels of the toxin have been sardines and anchovies—planktivorous fish that consume phytoplankton. Consumption of these fish has resulted in the stranding and death of marine mammals and sea birds on the West Coast of the United States. So far, these are the only known poisoning victims of this toxin. Domoic acid has seriously impacted razor clam recreational fisheries (and its support industries) in Washington State and commercial crab fisheries on the West Coast of the United States. In Nova Scotia, Canada, and Maine, very high levels of domoic have been detected in mussels. However, due to an extensive and successful monitoring and surveillance programs put in place since 1987, no human illnesses have so far been reported in these areas from consumption of commercially raised shellfish. Do-

moic acid is produced by some of the diatoms in the genus *Pseudo-nitzschia*. However, not all species have been implicated in major domoic acid poisoning outbreaks, so far these include: *P. multiseriata*, *P. australis*, and *P. pseudodelicatissima*. Globally, these organisms are quite cosmopolitan and have been identified in temperate waters of both the Northern and Southern Hemispheres. The genus is also fairly common in marine estuaries.

**Diarrhetic shellfish poisoning (DSP).** As the name implies, human consumption of shellfish containing the toxins associated with this syndrome causes diarrhea. Because symptoms are mild and similar to those in other common illnesses (gastrointestinal distress, nausea), many cases probably go largely unreported so that the true incidence of DSP is likely much higher than current epidemiological data indicates. However, there is a particular human health concern associated with DSP because the toxins involved (the dinophysistoxins or DTXs) are known potent tumor promoters (Fujiki et al., pp. 232–240). Toxic shellfish and causative organisms have been found in the Mediterranean Sea, off the Galician coast of Spain, and Ireland. *Dinophysis* cf. *acuminata* and *D. acuta* are believed to be the causative organism and are found in temperate waters worldwide. Recently, DSP toxins have been found in North America in eastern Canada and the northeastern coast of the United States but the primary source of the toxins appears to be *Procentrum lima* (Reguera et al., pp. 78–80).

**Neurotoxic shellfish poisoning (NSP).** People consuming shellfish containing the toxins report tingling fingers, numbness of lips, and reversal of temperature sensation, along with gastroenteritis. During heavy blooms of the causative organism of NSP, the dinoflagellate *Karenia brevis* (older name: *Gymnodinium breve*), aerosol dispersions of both the organism, and toxins can be caused by breaking waves and wind resulting in upper respiratory problems and distress in people. In some cases, victims may need to move inland to avoid exposure to the aerosols. The toxins involved are high-molecular-weight polyether toxins known as brevetoxins. *Karenia brevis* inhabits both temperate and tropical waters. In the United States, outbreaks are common in the Gulf of Mexico, where long-lasting blooms have been observed along the west coast of Florida. In the early 1990s, outbreaks of NSP were also reported on the North Island of New Zealand.

**Ciguatera fish poisoning (CFP, or tropical fish poisoning).** Symptoms, including gastroenteritis, that in most cases occur within a very short period of consuming the tainted fish. In severe cases, paresthesia or numbness occurs around the mouth, lips, and tongue. In extreme cases, burning sensations in mouth and death occur. Some victims report a reversal of the sensations of hot and cold. One victim was observed blowing on ice cream to cool it down. In some cases, symptoms reoccur years after the initial intoxication, usually during times of stress. In the most extreme cases of intoxication, death can occur within hours

of consuming tainted fish. The toxin, ciguatera, and its congeners are complex fat-soluble, high-molecular-weight, polycyclic polyether compounds. The toxins are produced by the benthic dinoflagellate *Gambierdiscus toxicus* that grows on corals and other surfaces in tropical reefs. Virtually all tropical reef-dwelling fish are suspect (Halstead, pp. 325–402). Coral-eating fish (e.g., parrot fishes) consume algae on the coral including the associated *G. toxicus*, thereby accumulating toxin in their fatty tissues. Predators of these fish then concentrate the toxin. Top reef predators, such as barracuda in the Caribbean and moray eels (in the Pacific), are considered high-risk vectors of ciguatera. Tropical Pacific outbreaks of Ciguatera appear to be the most intense and have caused rapid deaths, while outbreaks in the Caribbean seem to be relatively mild. Treatment is largely symptomatic, entailing fluid replacement and other life support measures. Unfortunately, monitoring tests for Ciguatera toxins are complex and costly and have not been widely implemented.

### Prevention, Control, and Mitigation

With all these intoxication syndromes, shellfish and fish show no clear outward signs that they might be poisonous. The presence of toxins can only be determined by appropriate chemical testing. Cooking, cleaning, or organ removal in fish and shellfish may reduce the toxin levels in some cases but cannot guarantee that the seafood has been rendered safe. Therefore, both recreational and commercial fishers must rely on monitoring and surveillance programs, usually operated by governmental agencies. Commercial seafoods, particularly shellfish, are usually monitored and tested for toxins (when reliable methods exist) as part of government safety and sanitation programs. It is wise for consumers to purchase only inspected shellfish from reliable, licensed retailers, since these businesses are usually required to maintain certification records for their shellfish stock.

For recreational fishers, it is vital that they obtain information about local closures or safe beaches. Necessary safety information should be posted on signs or made available by telephone “hotlines,” websites, or news media. Unfortunately, depending on agency resources, recreational and private beaches are monitored in a more limited fashion, placing these fishers at a higher risk. Nevertheless, it is the recreational fishers’ responsibility to obtain the needed information that will allow them to safely enjoy the sea’s bounty.

**ALLERGIES.** Food allergy has been recognized since the time of Hippocrates. People with adverse reactions to food can be difficult to evaluate because overlap exists between true food allergy and toxic and other reactions to chemicals or other food ingredients. The incidence of food allergy is increasing in the industrialized world, raising questions about the interactive effects between environmental and genetic factors. There is a considerable burden on society in terms of cost of treatment, death from anaphylactic reactions, and the anxiety produced by real or perceived food allergy. Avoidance of the food is the current treatment, but new strategies are being developed.

### Definitions

Adverse reactions to the ingestion of food that can be reproduced is termed intolerance or hypersensitivity. Since this does not imply an underlying cause, it may encompass immune or nonimmune mechanisms. For example, chemicals such as caffeine may cause reproducible symptoms, but this is not mediated by the immune system. True food allergy or food hypersensitivity is defined as a reproducible adverse reaction to food caused by the immune system creating antibodies or cellular inflammation.

**Type I IgE-mediated food allergy.** The classic example is immediate anaphylactic reaction to food. In susceptible individuals after exposure to the food, the immune system creates specific IgE antibodies to that food. IgE is produced by the immune system’s B-lymphocytes, and is bound to receptors on the surface of mast cells. Mast cells reside in tissues at body surfaces such as the skin, eyes, nose, throat, lung, and gastrointestinal tract. Mast

cells are made up of granules containing chemicals including histamine. When the food protein contacts and binds to adjacent specific IgE molecules at the mast cell surface, a cascade of events occurs leading to degranulation of mast cells and release of chemicals that cause the allergic reaction. This may include skin hives, airway swelling, wheezing, abdominal pain, vomiting and/or diarrhea. This may progress to anaphylaxis, shock, and even death. This reactivity to food can be demonstrated by skin-prick tests, which have been used to diagnose allergy since the 1870s. Food protein is placed on the skin, the skin is scratched or pricked, and a hive will develop in the presence of skin mast cells with IgE directed against the food. In the 1920s Prausnitz and Kustner showed that a substance circulating in the blood of the allergic individual was responsible for a positive skin test, because blood serum could be transferred to the skin of a nonallergic individual resulting in a positive skin test. IgE is that substance, and food-specific IgE can be measured directly in the blood, by means of the IgE RAST (radioallergosorbent) test. Diagnosis of this immediate type of food allergy rests on the history of rapid onset of symptoms, demonstration of positive skin-prick test or specific IgE RAST. Challenging an individual with the food is the ultimate way to prove a food allergy.

**Non-IgE-mediated food allergy.** Other immune mechanisms can be responsible for allergic reactions to foods. The classic example is celiac disease (celiac sprue or gluten-induced enteropathy). This is an immune system reaction to wheat (gluten). Patients do not have IgE antibody directed against wheat, but exposure to gluten over a period of time causes inflammation of the intestine and a characteristic atrophy or flattening of the normal intestinal villous folds. The diagnosis rests on the characteristic biopsy of the small intestine coupled with another type of antibody (IgA) against wheat protein. Any food may also cause similar intestinal inflammation, leading to varying symptoms and signs depending on the area of the intestine affected. Unlike IgE-mediated allergy or celiac disease, there are no readily available confirmatory tests for these other food allergies.

### Prevalence

Food allergy is perceived as being common; however, large studies support the idea that true food allergy is less common than people think. A study of 480 infants from birth to age three revealed 28 percent were suspected by their parents as having food allergy; however, this was confirmed in only 8 percent of this group. The prevalence then decreases with age. Twenty percent of adults suspect food allergy, though allergy is confirmed in only 1 to 2 percent of adults. Although food allergies in adults tend to persist with age, many infants and children outgrow them with time.

Recently, interest has grown over the apparent increase in the prevalence and severity of food allergy. This has paralleled an increase in other atopic disorders such

as asthma in industrialized nations compared with children of similar genetic background in developing countries (atopic refers to a tendency to develop allergic conditions such as hay fever, asthma, or food allergies). The “hygiene hypothesis” contends that through evolution, the human immune system has developed with a specific microbial environment, and reduced exposure to microbes in the developed world may lead to increased allergic response. Further study is needed.

### Type I Immediate (IgE-Mediated) Hypersensitivity Reactions to Food

Immediate hypersensitivity reactions to foods are most common in young children, with 50 percent of these reactions occurring in the first year of life. The majority is from cow’s milk and soy protein from infant formulas. Other foods begin to predominate in older children, including eggs, fish, peanuts, and wheat, and along with milk and soy account for over 90 percent of food allergy in children. Peanut, tree nut, and shellfish allergy predominate in adults. Exposures may occur inadvertently due to improper labeling, changes in product composition with time, and contamination of foods during processing. Symptoms from multiple organ systems may occur, beginning within minutes. Unfortunately, fatal anaphylactic reactions (shock) to food occur despite strict dietary avoidance and treatment of reactions. Families, caregivers, and individuals with a history of anaphylaxis to food require education in diet and in the use of self-administered epinephrine. Individuals should be observed in a hospital setting after a significant reaction. Exercise-induced anaphylaxis to food occurs when the combination of ingesting the food followed by exercise leads to anaphylaxis. Oral allergy syndrome describes symptoms of itching of the mouth and throat often attributable to eating fruits, and typically does not progress. Chronic hives or urticaria can be caused by foods, but it is a common misconception that these conditions are usually food-related; only in 1 to 2 percent of cases is urticaria or chronic hives a reaction to food. Atopic dermatitis (AD) or eczema is a chronic skin condition found in atopic individuals. Patients with AD have a 30 to 40 percent prevalence of food allergy.

**Investigation and treatment of type I immediate reactions to food.** The rapid onset of symptoms after ingestion correlates highly with positive skin-prick or IgE RAST tests to the offending food, making confirmation of immediate hypersensitivity straightforward. Consultation with an allergist and dietitian is recommended. Groups such as the Food Allergy and Anaphylaxis Network can provide support and educational materials.

### Non-IgE-Mediated Food Allergy

The spectrum of non-IgE food allergy is quite varied, and the symptoms often parallel the area of inflammation in the gastrointestinal tract (see sidebar). Avoidance of the food will resolve symptoms and intestinal inflammation;

### ***Manifestations of IgE Allergy to Food***

Cardiovascular (shock)  
Respiratory (wheeze, cough)  
Gastrointestinal (acute vomiting, pain, diarrhea)  
Skin (hives, atopic dermatitis)  
Eye (itching, swelling)  
Oral (itching, swelling)

### ***Manifestations of Non-IgE Allergy to Food***

Growth delay  
Protein-losing enteropathy, edema  
Iron-deficiency anemia  
Chronic diarrhea  
Eosinophilic colitis  
Chronic vomiting/feeding intolerance  
Food protein-induced enterocolitis syndrome  
Atopic dermatitis  
Infantile colic

### ***Manifestations of Celiac Disease (Gluten-Induced Enteropathy)***

Growth delay  
Chronic diarrhea  
Abdominal distension  
Abdominal pain  
Dermatitis herpetiformis  
Associations: Diabetes, thyroid disease, Down syndrome

rechallenge with the food will reproduce the injury. However, unlike IgE food allergy, symptoms may take days or weeks to resolve or reappear with elimination or exposure respectively, making evaluation even more difficult.

Celiac disease or gluten-induced enteropathy (see sidebar) is a chronic intestinal condition caused by non-IgE mediated allergy to gluten, a protein in wheat and other grains. Chronic exposure to gluten causes inflammation and atrophy of small intestinal folds, leading to symptoms of malabsorption of food. Typically, patients have diarrhea, weight loss, and abdominal bloating. There is a genetic predisposition to celiac disease, but onset may occur at any age, suggesting an environmental factor such as infection may be needed in some individuals to trigger the inflammatory process. The disease has a higher prevalence (up to 1 in 400–500) in individuals of eastern European descent. Celiac disease is associated with a skin condition (dermatitis herpetiformis), thyroid disease, diabetes, and Down syndrome.

Allergic or eosinophilic colitis in infants is a common manifestation of non-IgE food protein allergy. It is characterized by diarrhea with blood and mucus. It is

caused by milk or soy formula and may occur in breast-fed infants from dietary antigens transmitted through breast milk. Colon biopsy shows allergic inflammation.

Food protein-induced enterocolitis is a severe reaction to food, often delayed four to six hours, without evidence of IgE. Patients present with lethargy, vomiting, and diarrhea. Recovery is within six to eight hours after fluid resuscitation. A careful history usually reveals the offending food, although this may not be appreciated unless multiple episodes occur.

Chronic enteropathy from food allergy can also lead to inflammation with villous atrophy similar to celiac disease. Most patients have diarrhea, in addition to weight loss, anemia, and low albumin from protein loss from the intestine.

Allergic gastritis is inflammation of the stomach with pain and vomiting. As with other non-IgE food allergy, biopsies of the stomach demonstrate allergic (eosinophilic) inflammation.

Allergic esophagitis is characterized by intense eosinophilia of the esophagus on biopsy. Patients complain of pain and problems with swallowing, even to the point of having food impactions in the esophagus. Treatment with hypoallergenic formula has been shown to improve esophagitis in infants; however, older children and adults may require corticosteroid medication.

Infantile colic and excessive irritability can be symptoms related to allergy in a subgroup of infants. By definition, colic is a condition with increased crying behavior in infants, for which no cause can be found. However, since allergy can potentially lead to inflammation and pain, formula allergy is often considered.

Attempts have been made to associate a variety of other problems with food allergy including joint disease, migraine, and behavioral and developmental disorders such as autism. Causal relationship between food allergy and these disorders remains unproven.

***Investigation and treatment of non-IgE-mediated food allergy.*** The diagnosis rests on the resolution of symptoms and/or biopsy findings on an elimination diet, with a return of symptoms on rechallenge. Unlike the rapid response characteristic of IgE-mediated disease, a prolonged challenge may identify delayed reactions with predominantly gastrointestinal symptoms up to six days after exposure. Elemental diets can be used to eliminate dietary protein antigens completely, then systematic rechallenge of the patient with suspected offending foods. As with IgE food allergies, avoidance of the specific food remains the mainstay of therapy.

### ***New Frontiers***

There are a number of exciting areas of research into the prevention and treatment of food allergies. Recent reports suggest that the allergic response can be altered by promoting beneficial gut flora (“probiotic therapy”). It

has also been discovered that only a few sites (epitopes) on food protein molecules interact with the immune system to create an allergic reaction. Genetic engineering of foods makes it possible to alter these epitopes, creating crops that are “nonallergic.” More study is needed to ensure that altering food proteins does not lead to other health concerns or different types of allergy. Other studies are under way to assess the effectiveness of promising new drug therapies for patients with food allergy.

#### AMERICAN INDIANS.

*This entry includes two subentries:*  
Prehistoric Indians and Historical Overview  
Contemporary Issues

#### PREHISTORIC INDIANS AND HISTORICAL OVERVIEW

Native North Americans consumed a variety of foods based on the diverse plant and animal communities found throughout the continent. Regional variation in diet paralleled regional variation in the availability of these food resources. This generalization applied until around 7000 B.C.E. This entry provides an overview of Native American diet, from the northern border of Mexico to the High Arctic, from the earliest peoples in the continent to the time of European contact.

#### Sources of Information

How do we know about the diets of past peoples? There are three main sources of information, each with its own limitations. Working backward from the time of European contact, there is recorded information about diet. The first European people to travel to the New World provided some information about native customs, but much richer information was provided by the first Europeans to live in the New World. These people (missionaries, explorers, and early settlers) were able to record information about foods and other customs before cultural disruption altered diet and subsistence. Because contact and early settlement was more often in coastal areas or along major watercourses, there is more information about coastal peoples. By the time Europeans had made their way inland, they were already encountering cultures changed by waves of impact from coastal regions. For example, the fur trade resulted in alterations in hunting practices among northern peoples before any Europeans were able to witness daily life in some inland northern villages.

A second source of information is ethnography and oral tradition. Ethnographic information comes from anthropologists who lived among native peoples and recorded their customs, including food procurement, preparation, and storage. A vast amount of ethnographic information was collected early in the twentieth century. Since this type of study represents only one or a few points in time, it is also helpful to learn the oral traditions of people, since these can reveal long-held customs and practices.

Insights into past diets are also provided by archaeology. Archaeologists analyze remains of food items including animal bones, charred seeds and cobs, pollen, and phytoliths (siliceous secondary cell walls of certain terrestrial plants which leave a “signature” that archaeologists and paleobotanists can identify), and the tools used for food procurement and preparation (spear points, fish hooks, digging sticks, manos, and metates). Chemical analysis of human bones provides direct information on foods consumed.

There are possible errors in all of these sources of information. Historians may only record what was eaten during a particular season. Ethnographers may also miss some of the diversity of the annual round of foods due to limitations on time spent with a group of people, or variations from year to year. Some items are more likely to be preserved in the archaeological record than others (bone tools versus wooden tools; ceramic vessels versus baskets woven from fibers). However, food preferences are strongly ingrained in cultures and so it is reasonable to assume that the habits that were observed by ethnographers and early historians and that are repeated in oral traditions can be extended back into time. The exception is that a major transition, plant domestication, took place prehistorically. The timing of this transition has been studied intensively by archaeologists and physical anthropologists.

## The First North Americans

The first people to enter the New World are thought to have come from northeast Asia and are usually characterized as “big game hunters.” During the late Pleistocene, large terrestrial mammals such as mammoths and mastodons were hunted, as is apparent from the association of projectile points and bones from these animals. Here researchers encounter the problem of bias in the archaeological record. Did these people only eat big game? The ethnographic information on northern peoples of the boreal forest and Arctic regions points to an emphasis on meat in the diet, and indicates that animals with fatty meat (moose and beaver) were preferred over lean animals such as hare. A number of different types of berries were collected in summer and some were preserved, but they con-

stituted a small percentage of the total diet. As the early Asian migrants to North America moved south, they hunted other large mammals, such as bison, and they probably learned about local plants and animals. In the arid Southwest, the archaeological record is less biased toward animal remains since wood, plant fibers, and seeds are preserved by the dry conditions. The descriptions of regional diets that follow are derived from a combination of archaeological, ethnographic, and historical information. (For additional information, the reader is referred to the *Handbook of North American Indians*, which presents information on the archaeology, ethnography, linguistics, geography, and history of various regions.)

A few generalizations can be made about the diet of North America’s native peoples. The edible plants and

animals that are available locally constituted the diet everywhere until the beginning of the practice of plant domestication, around 7000 B.C.E. In areas where plants were domesticated, or where domesticated plants were introduced from Mexico and Central America, locally available food resources continued to be used, but were supplemented, to varying degrees, with domesticated plants. It takes approximately 120 days for a crop of Indian corn to mature. This means that in much of Canada, where the growing season is less than 120 days, cultivation of corn was not possible, and diet continued to be based on locally available resources. There is evidence of maize cultivation in the southern portions of several provinces, including Manitoba, Ontario, and Quebec. Farther north, there was an increasingly heavy reliance on foods of animal origin. Other areas, including the Eastern Woodlands and West Coast, had plentiful and diverse foods available and continued to make use of those resources after the introduction of horticulture.

### Arctic

Among Arctic peoples, diets varied depending on proximity to the coast. Those in coastal regions relied on sea mammals and fish. Sea mammals were more important in the High Arctic, where they were hunted in the frozen sea. Fish were more important in the warmer regions where there is more open water. Inland groups relied on migrating caribou, smaller terrestrial mammals (hares), birds, eggs, and berries (salmonberries, cranberries, and blueberries) and roots (cotton grass root and licorice root) (Ray, 1984). While dietary diversity was greater than is generally assumed, Arctic peoples, who are well adapted to metabolizing foods high in animal fat, relied primarily on hunting. Fat is essential as a source of lightweight, storable energy for functioning in cold climates and with periodic food scarcity. Cooking was not routinely carried out among Arctic peoples since fuel is a scarce and precious commodity. Meat was usually eaten raw and fish were dried before eating. From a nutritional perspective, this means that a number of vitamins, including vitamin C, that would otherwise be lost in cooking, were available. Internal organs were also eaten, adding to the supply of vitamins and minerals.

### Subarctic

In the Subarctic boreal forest there was also a heavy reliance on animal foods in comparison to plant foods. Large terrestrial herbivores, such as caribou and moose, were hunted, along with small mammals. Fish were also an important food source. Although native people did not domesticate caribou, the migration routes were well known, and caribou drives, in which the animals were herded into enclosures, allowed for large-scale hunting. Among the Hare people of the Northwest Territories, foods were cooked either by roasting or stone boiling. Some favorite dishes included caribou tongue, caribou fetus, muskrat, and beaver tail (Savishinsky and Hara, 1981, p. 317). Meat and fish were preserved either by smoking,

drying, or freezing. A food that was common throughout the Subarctic and on the Great Plains is pemmican, which is made by pounding dried meat or fish with fat and sometimes with berries.

### Northeast and Southeast

The peoples of the eastern Woodlands enjoyed a wide variety of both animal and plant foods. An assortment of nuts (hickory, walnut, and chestnut) were collected and served as one source of protein and fat. They could be stored over the winter and were used in a number of different ways. Among the Cherokee, nuts were pounded, then boiled, and the resulting milk was added to other foods such as corn. Fruits such as apple, cherry, peach, plum, and crabapple were used along with numerous wild greens, including dandelion, Solomon's seal, and bergamot, and berries (blackberry, strawberry, wild grape and huckleberries) (Chiltoskey, 1975). Animal foods included deer, rabbits, squirrels, and fish. Maize (corn) was introduced around 200 C.E., and it gradually became a staple (in breads, soups, and as roasted ears) to which other foods were added.

Researchers have determined that native plant species were domesticated prior to the introduction of maize in eastern North America. Sometime between three and four thousand years ago, indigenous plants were cultivated by people in the American mid-continent and Northeast. These plants include sumpweed (*Iva annua*), goosefoot (*Chenopodium berlandieri*), and sunflower (*Helianthus annuus*) (Smith, 1992). Goosefoot bears starchy seeds while sump weed and sunflower bear oily seeds. By 800 C.E., maize increased in importance relative to indigenous seed plants, and this was accompanied by an increase in population density in the American Midwest, Southeast, and Northeast.

### Great Lakes

The area around the lower Great Lakes supported a large population of Iroquois and related groups, and has been studied extensively by early historians, Jesuit missionaries, ethnographers, and archaeologists. In addition, many descendants of those native groups still reside in the area. In 1916, F. W. Waugh published a monograph titled *Iroquois Foods and Food Preparation*, which provides detailed information on agricultural practices and utensils used in gathering, preparing, and eating foods, along with numerous preparation methods for various foods. Two commonly eaten foods among the Iroquois, historically, were corn bread and corn soup. Bread was made by pounding corn into flour. Boiling water was poured into a hollow in the flour. Additional ingredients may have included dried berries (huckleberries, blackberries, strawberries, elderberries), cooked beans, and nuts. A lump of the resulting dough was patted between the hands then dropped into boiling water. Prior to the introduction of copper kettles by Europeans, bread was more often baked under hot embers or on heated stones. The bread was

Cliffside pueblo of the Anasazi people in Mesa Verde National Park.

often eaten with maple sugar or syrup. The most common food at the time of historic contact was *sagamité*, a thick corn-based soup. From the basic corn broth, bits of meat or fish were added. Sometimes beans were also added. This meal would supply all essential amino acids and is a good source of carbohydrates.

### Northwest Coast

The Northwest coast includes the land between the Pacific Ocean and the coastal mountains from the Bay of Alaska to southern Oregon. Food resources there are very rich, with abundant waterfowl, migrating sea mammals, and both marine and anadromous fish. In addition, over 550 different plant species have been documented as food items. Harriet Kuhnlein and Nancy Turner's *Traditional Plant Foods of Canadian Indigenous Peoples: Nutrition, Botany and Use* (1991) covers all of Canada but with special reference to the Canadian Northwest coast. Their detailed descriptions of plant use and the nutritional value of various plant foods provides ample evidence of an archaeological bias that overestimates the importance of animal foods in the diet. Interestingly, Native Americans did not differentiate between plants used for food and those used for medicine, since some foods were eaten as a form of medicine.

### California, the Great Basin, and the Plains

Peoples of interior California and the Great Basin relied on fish, local game, and a variety of seeds. They also ate insects such as ants, roasted grasshoppers, caterpillars, fly larvae, and seventeen-year cicadas (locusts) (Bodenheimer, 1951). Food was stored in pits, and cooking was generally achieved by roasting. Pine nuts were ground into a flour that could be stored and easily transported (Kehoe, 1981). Along the southern periphery, agricultural crops included maize, beans, and squash.

The Great Plains extends from southern Canada to Texas. Along the eastern margins and along the major rivers, native people practiced small-scale horticulture. Hunting was important throughout the Plains, and there is evidence of big-game hunting among the early Clovis people, and later evidence of bison hunting through controlled drives over natural features such as cliffs and arroyos (Frison, 1998). There is archaeological evidence of long-term storage of meat from such drives. Ethnographic work as well as evidence from pollen and phytoliths indicate that a wide variety of indigenous plants were used, including plums, grapes, rose hips, berries, turnips, and camas root (Wissler, 1986).

Bison meat and fat were desirable food items. There is both archaeological and nutritional evidence for selective hunting of fatter animals (not only bison, but other large mammals as well). Meals are both more satisfying and more economical when protein is accompanied by fat and carbohydrate, a readily available source of energy that spares the higher metabolic demands required to break down protein. Other animals were also hunted for food, including deer, antelope, rabbits, and hares. Pemican was a staple food for many Plains peoples. Foods were cooked either in earth ovens lined with heated rocks, or by boiling in hide bags with heated rocks inside.

Farming was also practiced by Plains peoples, particularly along the eastern margins and along the Missouri and Mississippi Rivers. Maize, beans, and squash were cultivated, and there is also evidence of the cultivation of the indigenous species, goosefoot, marsh elder, and sunflower, similar to the Eastern Woodlands.

### Southwest

The American Southwest is of special interest for two reasons. First, the earliest evidence of domestication of maize, beans, squash, and other Mesoamerican cultigens is found there. Second, due to the hot and dry climate, plant remains are preserved in the archaeological record, providing a less biased picture of past diet than in other regions of North America. Spectacular Anasazi villages that flourished from 900–1300 C.E., such as Chaco Canyon, Mesa Verde, and Canyon de Chelly, housed people who farmed in canyon bottoms and on mesa tops with the aid of irrigation (Cordell, 1984). The Anasazi also exploited antelope, white-tailed deer, jackrabbits, cotton-tailed rabbits, and wild turkeys. Along the eastern margins, maize was traded for meat with Plains peoples. Food was prepared in earth ovens, in ceramic vessels, and on open fires. Indigenous plants used for food include piñon (pine) nuts, prickly-pear cactus buds, amaranth seeds, mesquite pods, and the heart of the agave (Cordell, 1984). *Zuni Breadstuff*, an early ethnographic account of all aspects of Zuni food, is a valuable source of information (Cushing, 1920).

### Impact of European Contact

Sustained European contact altered traditional foods and food preparation throughout North America. Metal

cooking pots were introduced, altering traditional roasting and boiling practices. The introduction of the horse had a profound impact on hunting techniques, particularly on the Great Plains. The fur trade altered traditional subsistence practices in the north. Displacement of native peoples by European settlers was very disruptive since an intimate knowledge of local environments was so important to obtaining food. Finally, the exchange of foods between the Old and New Worlds had a profound effect on cultures on both sides of the Atlantic Ocean (Crosby, 1972).

## CONTEMPORARY ISSUES

The terms "American Indians" and "Native Americans" (both are appropriate) refer to diverse groups of indigenous peoples that have occupied the area north of Mexico and south of Canada since at least 12,000 B.C.E. With more than 550 sovereign Indian Nations currently residing within the political boundaries of the United States, summarizing their different foods and foodways is difficult. Such an undertaking would be analogous to characterizing "European foodways" as though Europeans from Italy to England were a homogeneous group. However, it is still possible to discuss some general characteristics organized along geographic lines.

Over several millennia the foodways of Native Americans were well established and included both wild and domesticated foods, traditions that have continued to evolve through the centuries of conquest, assimilation, and resistance that began with European contact in the fifteenth century. Contrary to popular stereotypes, not all Native Americans were horse-riding bison hunters who lived in tepees. Although these elements fit some historical contexts, they ignore actual regional and cultural differences.

Given the extensive ethnographic record of American Indians and the great interest the public has in their lives, it is surprising that so little research on their foodways has been done. A great deal of work on the ethnobotany of plants they used was done in the late nineteenth and early twentieth centuries, but it often focused on the potential economic importance of the plants as food and medicine, not on their importance as foods in specific cultures.

Both hunting and gathering (foraging) made important contributions to the diet of all American Indian groups at the time of contact, whether they were horticulturalists or not. The fact that no large mammals (horses, cattle, pigs, sheep, and goats) were domesticated in Native North America—only to be introduced later by Europeans—explains in part why foraging remained important. Virtually every native plant and animal species was used to some extent for food, medicine, and/or manufacture. Animal domesticates did include dogs, turkeys, and ducks, while domesticated plants included several varieties of maize (corn), beans, squash, gourds, sunflowers, sumpweed, and goosefoot (*Chenopodium*). Maize was a central food in the diets of many regional groups, and, except for California, was grown just about everywhere it was ecologically viable. The cooking traditions of Native Americans included everything from stone-boiling in leather bags to roasting and baking in earth ovens.

Because of a mixed subsistence pattern for horticultural groups, it is not surprising that both wild and domesticated foodstuffs remain traditional American Indian foods. The extent of this relationship is recognized in rights guaranteed by treaty to forage (hunt, fish, gather)

many species that are restricted by season or prohibited to non-Indians.

### Traditional Native American Culture Areas

Native Americans have been traditionally divided into several culture areas related to shared geographic and environmental boundaries. This is not to say that peoples falling within these realms were all culturally the same. However, both the historical experience of these groups as well as their ways of adapting to each area have heavily influenced their traditional foodways. Regardless of academic debates about the use of the cultural-regional approach, it remains a useful way to organize the regional differences that define Native Americans and their foods. Although the focus here is the American Indian groups south of Canada and north of Mexico, there is a great deal of overlap with cultures to the north and south. Also, in addition to the hundreds of federally recognized tribes in the United States, there are dozens more who maintain cultural traditions that are not federally recognized. A few contemporary issues for each area will be discussed, but no attempt will be made to detail the foodways of specific cultural groups.

Fry bread (bread dough deep-fried in fat) is a popular food at Indian fairs and gatherings, but it is also the cause of obesity and diabetes among native Americans. The dish can actually be traced to medieval Europe. © PHIL SCHERMEISTER/CORBIS.

**Eastern Woodlands.** Comprising the Northeast, Great Lakes, and Southeast United States, this area extends from the Atlantic Coast west to the eastern prairies, north to the Canadian border, and south to the Gulf of Mexico. It is a place where corn, beans, and squash, all originally from Mexico, were the central staples of life and identity. Communities ranged in size from the small dispersed villages of New England to the large urbanized mound-building cities along the Mississippi and Ohio River valleys. The degree of maize dependence varied from area to area, but its central importance to this region's Native Americans is undeniable. Maize is a fundamental element of their folklore and origin myths.

Early European colonists in eastern North America rapidly incorporated various Native American dishes into their diet. Some of the best-known examples are those of Algonquin-speaking peoples, with some alterations of the original names and meanings. "Succotash," a corrupted version of the Narragansett "misickquatash," refers to whole kernels of grain. It is often a mixture of green corn cut from the cob, beans, and perhaps another ingredient, which might be anything from meat to squash. Hominy, or "rockahominy," is made by taking shelled ripened corn and soaking it in an alkaline solution made from wood ash or lye to remove the hulls. This method also enhances the nutritional value of the maize product. Throughout the United States it is sold as yellow or white hominy or under its Latin American name, "pozole." When dried and milled into coarse bits, it is called "hominy grits." In some areas of the Southeast, however, the term "hominy" can also refer to grits.

Although maize is an important food item in the Great Lakes region, the gathering of wild rice takes precedence there because it is essential to maintaining the identity of many cultures in this area. In fact, in many states only American Indians can legally gather true "wild" rice (*Zizania aquatica*). Given the constant demand for this product in American cooking, it continues to be a profitable resource for these communities. Many of these groups have also been in conflict with U.S. federal agencies, environmental groups, and local non-Indian communities over their legal spearfishing rights.

From the Iroquois nations of upstate New York south to the Cherokee of the Carolinas and the Seminoles of Florida, traditional foodways for nations of the Eastern Woodlands still combine locally gathered foods with the overarching importance of what the Iroquois refer to as the "Three Sisters": corn, beans, and squash. Across this region green (unripened) corn is the central element in "Green Corn" ceremonies, including the *Busk* ceremony of the southeastern cultures, which signals the beginning of a new year, and the annual *Schemitzun* (Green Corn Festival) of the Mashantucket Pequot held near Ledyard, Connecticut, which gathers nations from across the country for a huge powwow. Green corn is now a major item of American foodways when consumed

as sweet corn, a mutated variety of maize that concentrates a sugar rather than a starch component.

**Great Plains and Rocky Mountains.** Bison, or buffalo, were a central food item and cultural symbol to many of the peoples of the central and western regions of North America. The meat was often processed into pemmican, a dried pounded meat often mixed with fat and chokecherries. This foodstuff was stored in parfleches (leather pouches) and could sustain a mobile population for long periods of time. The introduction of the horse in the eighteenth century greatly transformed the nomadic bison hunters of these regions, including groups that engaged in seasonal small-scale horticulture as well as those who did not but traded meat for maize with horticultural societies to the south and east. The horse also facilitated the migration of groups from the eastern prairies, like the Sioux, who gave up horticulture to live in tepees and become bison hunters. They were not only able to traverse great distances, but their mobility gave them the opportunity as warriors to resist assimilation well into the late nineteenth century, when almost all other Native American groups had been placed in some type of reservation system. Their dependence on bison was also their downfall because those animals were systematically slaughtered to the brink of extinction by white men, a destruction greatly facilitated by the completion of the transcontinental railroad and U.S. policies intended to starve them into submission by eliminating their food supply.

Bison remain central to Native American cultural identity. In the Dakotas and Montana some groups have begun to raise large herds of bison on the great expanses of grassland that they once occupied. A market that demands a low-fat alternative to beef, which bison meat provides (for example, buffalo burgers), has made raising them economically valuable.

Annual gatherings at the time of the traditional bison hunts in the summer months led to the importance of powwows or social get-togethers that are still held. The dance style of the plains groups is at the core of a powwow circuit that involves Indian nations from all over the United States. These events have also spread foods central to pan-Indian identities, for example, fry bread.

**Southwest.** Traditionally home to pueblo farming communities and bands of foragers, this desert region exemplifies Native Americans' ability to adapt to extreme environments. The same triad of corn, beans, and squash was also central to these groups, along with a host of plants gathered from the deserts and mountains. Unlike many Native American groups who were forcibly removed from their traditional homelands, Southwest farmers from New Mexico to Arizona have been able to maintain an ongoing relationship with lands that they have cultivated since prehistoric times. Groups like the Hopi continue to practice dry-land farming in the desert of northeastern Arizona, and perform cycles of elaborate rituals to bring rain and fertility to their lands. Throughout the Southwest, water

rights are a major point of concern for Native Americans whose livelihood is based on range livestock and irrigated crop production. They compete for water with growing urban centers like Albuquerque, New Mexico, and Phoenix, Arizona. The use of water by mining operations exacerbated the scarcity and critical need for this finite resource.

Even peoples who were traditionally known as foragers, like the Navajo, over time incorporated horticulture. With the introduction of sheep into the region, they continued to adapt to the desert by becoming herders. Since the 1930s the Navajo have suffered through a number of government-imposed livestock reduction programs meant to limit overgrazing of the fragile desert grasses and forage, and they continue to resent and resist attempts to regulate their livelihood and important source of food. By continually adapting to both the desert environment and changing political climates, the Navajo Nation, which completely surrounds the Hopi Nation, is the largest group of American Indians in the United States, with a population of well over 300,000.

In the harsh Sonoran Desert of southern Arizona, groups like the Tohono O'odham (Papago) and Akimel O'odham (Pima) combine ancient agricultural traditions using irrigation canals with foraging for desert plants. For example, bean pods from the mesquite tree are picked and then pounded into flour, and the fruits of the saguaro cactus are collected and boiled down to make a syrup, which was also fermented and used traditionally as a ceremonial wine.

Chili peppers, a New World cultigen from Mexico, were introduced into the Southwest by the Spanish and became central to many regional cuisines.

**California, Great Basin, and Plateau.** Although California is known today as a major U.S. food-producing area, in the past it was home to foragers who utilized the diverse natural ecosystems of the region (e.g., their annual gathering of acorns that were processed into flour). Many groups utilized the rich coastal resources, too. This pattern ran from the Baja region in the south north to areas that overlapped with the Northwest Coast native peoples.

Native Americans from the Great Basin area survived well into the twentieth century as foragers in one of the most extreme environments that humans inhabit on earth, the Mojave Desert, including "Death Valley." Communal rabbit and grasshopper drives brought together greatly dispersed bands. A variety of desert plants were also collected. Shoshonean groups in Nevada have found it difficult to maintain many of these traditions in areas where nuclear testing and uranium mining have destroyed ecosystems.

Groups from the Plateau region of the United States are located in an area that overlaps traditions from the Great Basin, Northwest Coast, and Northern Plains. The gathering and preparation of the camas tuber (*Camassia*

*quamash*), a type of lily, links groups like the Nez Percé to their traditional foodways.

With the vast environmental diversity of these regions, mining, logging, and commercial fishing enterprises threaten the ability of many Indian nations to continue their traditional food-getting activities. Such operations not only destroy local ecosystems but areas that are considered sacred as well.

**Northwest Coast.** Native American fishing and whaling communities along the Pacific coast from northern California to southeast Alaska provide a unique example of sedentary foragers who utilize both aquatic and terrestrial species of plants and animals. Salmon was a central element of their diet, smoked and also processed for oils, and provided a great source of wealth for these peoples. The anadromous nature of salmon—swimming downstream to the ocean from their birthplace and then returning to it to spawn at the end of their lives—provided an abundant and predictable source of food, allowing these foragers to become sedentary dwellers along the salmon runs. Salmon continues to be economically important to these peoples.

The operation of commercial fishing fleets as an extension of their traditional food-getting activities continually places American Indians on the Northwest Coast in direct conflict with the non-Indian commercial fishing industry as well as with U.S. federal agencies regarding their fundamental right, guaranteed by treaty, to secure a livelihood. A conflict over whale hunting has also emerged. Ever since gray whales were removed from the endangered species list, some groups, like the Makah, have petitioned and won the right to conduct traditional whale hunts, to the disappointment of environmental activists who have attempted to stop them. The goal for Northwest Coast peoples is not necessarily to make whale hunting a commercial enterprise, but to engage in an important food-getting activity that has great symbolic meaning in their culture.

The Northwest Coast area is also known for the potlatch (etymologically unrelated to "potluck"), a great feast and giveaway. Wealth that was accumulated—salmon oil, for example—by the elite of a community was ceremonially given away to rival villages. Although reciprocity was an important dimension of the potlatch, gaining status and the display of a family's and community's wealth was the major point of the event. As in the past, totem poles are erected to mark the greatness of a potlatch. The potlatch remains an important community event that reinforces cultural traditions through dance, feasting, and sharing.

### Contemporary Diet and Nutrition Issues

Native Americans face a host of social problems (i.e. alcohol/drug abuse and violence) at levels far above the national average, and it is alarming that the rate of adult-onset (Type 2) diabetes for American Indians is over three times that of the rest of the U.S. population as a whole.

Explanations for this phenomenon have included the “thrifty genotype” model, which posits that such a genotype would have given a genetic advantage to populations who experienced periods of feast and famine. If, during periods of feasting, they were capable of maximizing their caloric intake of fat for storage, which could be tapped during times of famine, they would have a selective advantage over other populations. Greatly increased insulin production during feasting would facilitate this process. A problem occurs when the feasting, especially in the form of high-fat, carbohydrate-rich foods, becomes full-time. The result has been high rates of obesity, insulin resistance, and diabetes.

Understanding this phenomenon is a complex issue that involves changes in diet, more sedentary lifestyles, and a movement away from traditional diets and to activities that are known to be healthier. The epidemic rise in diet-related health problems like diabetes, coronary heart disease, hypertension, and obesity has been most pronounced in the decades following World War II. The promotion of an American diet and lifestyle as one of the many facets of attempting to assimilate Native Americans into the U.S. mainstream included home economics instruction for women showing them how to utilize the surplus commodities being provided to the impoverished Indian communities. Many of these foods left out a number of micronutrients available through traditional methods of processing. For example, stone-ground maize provided a good source of iron and other minerals. Ironically, the combination of commodities—highly refined white flour, sugar, and lard—are the basis of a common Indian food, fry bread. One would be hard-pressed not to find some variant of it in communities across the United States. Go to any powwow and fry bread power will be there. A variant that includes toppings like spicy ground beef and/or beans is called an “Indian taco.”

In general, the daily diet of most Native Americans does not contain traditional foods or foodways. Native Americans are just as much a part of the system of foodways as everyone else in the United States. For many, their diet reflects that of other low- to middle-income families who often buy food for its bulk, not its nutritional value. This is not to say that traditional foods are not important to their Indian identity; they are. Unfortunately, for many tribes these traditions continue to fade. The recent boom in casino gambling may benefit some groups, but the future will tell if the all-you-can-eat buffets found in most casinos represent cultural revitalization or loss.

A number of tribes have started educational programs on nutrition and campaigns that extol the benefits of their traditional foods. For example, O’odham groups (Pima and Papago) of Arizona, working in cooperation with Gary Nabhan and Native Seeds/SEARCH, have been attempting to reduce their incidence of diabetes and other diet-related health problems by promoting the growing and gathering of traditional desert foods. These

programs not only stress dietary change and physical activity but also emphasize the importance of cultural traditions. The history of Native American foodways shows that, when faced with challenges, Indian peoples adapt and change while maintaining their core identities. In many cases, even when the traditional language is no longer spoken or religious rituals are no longer performed, the knowledge of traditional foods has not been forgotten.

**ANCIENT KITCHEN, THE.** The traditional and symbolic heart of the home, the kitchen is inextricably linked with humankind's discovery of cooking food with fire. The use of fire has been known for over half a million years, as indicated by the remains of hearths in the Choukowntien cave in northern China. There "Peking Man" left traces of cooking around the hearth in the charred bones of numerous animals. Using fire for food preparation was a central culinary breakthrough. Some flavors are more palatable, and some foods are made edible, when cooked. The designs of hearths and ovens and the locations of kitchens through the millennia document the evolution of ancient kitchens. The English word "kitchen" comes from the Latin *coquere*, meaning to cook.

### Kitchen Design

Several related and important areas were located near ancient kitchens, including the pantry, orchard, garden, spice and medicinal herb garden, larder, icehouse, and root cellar. Ancient Chinese clay models of a household show the kitchen located near or even over the pigsty. Pigs were a main source of meat, and they provided manure for fuel and a convenient place for cleaning up any refuse from cooking and dining. In the fifth century B.C.E. ancient Greeks designed the kitchen as a separate house, and the layout continued in ancient Rome. The Romans built street stalls for quick snacks, but these were not kitchens in the full sense. Most wealthy Romans also owned country property, where grapes were pressed into wine, wheat was harvested, and olives were pressed for oil. The city kitchens provided space for these products. Kitchens were planned with clearly defined preparation areas.

Later medieval châteaux and wealthy European homes had spacious kitchens with several adjacent ante-rooms, including a room for utensils, a pantry, cold storage, and a buttery. For the middle class, kitchens continued as a location for communal cooking, dining, and social activities. Renaissance kitchens were often elaborate. As is common of the privileged throughout the centuries, the wealthy boasted the most modern devices for cooking, storage, and food preparation, from the spit to gridirons, ewers, salvers, and huge cauldrons. The kitchen was viewed as a workshop for food preparation for daily dining and feasts and also for preservation of food for the winter months. Ottoman kitchens of the

Turkish sultans in the sixteenth century provide another look at early kitchens of the wealthy. In the Topkapi palace in Constantinople, sultans' chefs had elaborate areas categorized for food preparation. European visitors were given a tour of the kitchen, which boasted eight-foot-wide cauldrons and large spits, and prepared food for thousands on a daily basis.

Nineteenth-century kitchens changed drastically with improvements in stoves and hearth designs. The kitchen remained a workplace, separate and distinct from the rest of the house. It was sometimes located in a separate building, in the basement (popular in Victorian times), or at the end of a long hallway. Temperate and hot climates alike moved kitchens outdoors. In India the Mogul kitchens were frequently located outdoors to remove the smells and heat of cooking from the living quarters. Moroccan kitchens placed cook pots in a "roofless kitchen," a walled enclosure off the pantry. Cool-climate Bulgarian homes have traditional summer kitchens used in the hot months.

### Social Use

Traditionally a woman, sometimes an older relative or matriarch, has been the cook. A woman's domain, the kitchen was also the focal point for transmission of culture and teaching younger family members and apprentices. Even the use of kitchen servants in wealthy households was tied to the housewife or housekeeper. Often the main point of connection between master and servant was between the mistress of the house and the head cook. The kitchen became a meeting place between classes; long-time family cooks were often treated with the respect due family members. In segregated societies the kitchen was a connection between whites and blacks where orders and desires were given.

### Kitchen Gods

In antiquity fire was sacred. A kitchen had an altar place for prayers and offerings to the kitchen god. Mexicans honor a patron saint of kitchens. The kitchen god Zaojing was revered in China, and Japanese cooks worshiped the god of fire. Similar examples abound.

### Food Storage

A great range of food and foodstuffs is available for most kitchens, and the size of the kitchen or complexity of tools does not dictate the quality or complexity of the cuisine. The earliest storage containers were animal skins, woven baskets, or gourds. Pottery's introduction allowed more variety of shapes and types of storage in a kitchen, from double-walled cooling jugs for water to tripod pots for stews and pointed amphorae for wine. Thus the larder and pantry became central to the design and layout of early kitchens. Root cellars kept foods cool and available during hot months and provided an even, temperate climate for preserves in the winter. The smokehouse adjacent to the kitchen was crucial for meat and fish preser-

vation. In Dutch homes the chimney had an ingenious bypass for the smoke, which allowed the cook to smoke meats at the same time. Ice and snow rooms in some cultures preserved food. Grapes were hung from rafters in Mediterranean kitchens and were preserved on the stem in water in glass jars in tsarist Russian homes. The many activities of preservation, canning, pickling, smoking, and drying all had places in early kitchens, as much of this work was done at home rather than in factories.

### The Stove and Hearth

Early hearths were clay or stone, and their main purpose was to enclose the fire. The risk of fire was always a worry. Fireplaces provided heat and light, and the fire required tending. Large homes had deep hearths, and foods were cooked in pots placed in banked coals or ashes. Fireplaces had rotating spits and hooks for hanging large pieces of meat. Domes gave way to hoods, with better ventilation. Russian and Dutch homes in the sixteenth century raised the hearths and created a sleeping platform around the fire. Some flat-topped Russian stoves also accommodated steam baths and drying laundry.

The invention and mass distribution of the large cast-iron stove, called the “iron sow” in early Sweden, radically changed the design of the kitchen. In the 1870s oil lamps replaced the light a fire had given, and the risk of the open fire was contained. Gone was the hearth as a symbolic and aesthetic part of the kitchen, replaced by a modern tool that required less tending and less space.

As 1900 approached, families previously self-sufficient in food production began to purchase more marketed foods. By the 1930s the need for large kitchen staffs and large kitchens was reduced in most homes. The smaller stove, the increasing availability of mass-produced foodstuffs, and a changing workforce reduced the size of pantries, even eliminating the need for root cellars and smokehouses. The kitchen was streamlined with only a hint of design nostalgia. While the kitchen changed, it remained the symbolic center of the home.

### ANCIENT MEDITERRANEAN RELIGIONS.

Religion shaped both the use and conceptualization of food in the Greco-Roman Mediterranean world. This was true of the consumption of animals, cereals, and other

plants. Because of the central role that food played in exchanges between gods and human beings, and between human beings themselves, food contributed to social and group identity. Ethnographers such as Herodotus distinguished Greek sacrifice from Persian, Egyptian, Scythian, and Libyan sacrifice; others distinguished Jewish and Christian rites. Ancient Greek religion located the practitioner in Greek culture and in a particular Greek community. This was important because by the end of the sixth century B.C.E., Greek cities were found around the Black Sea, along the coast of Asia Minor, in North Africa and southern Italy and Sicily—and after 300 B.C.E. in Syria, Persia, and Egypt. Similarly, as Rome came to distinguish itself from its Italic and Greek neighbors and to expand first throughout Italy and then throughout the whole Mediterranean world, it became necessary to establish how Roman culture might relate to cultures indigenous to the territory it now governed. There is ample epigraphic and literary evidence that people ate together in groups with religious affiliations throughout antiquity (*orgeones* in Greek, *collegia* in Latin), and that structures of power adapted the groups to reflect their influence, but did not greatly change the practices of eating. A major example is provided by the Ptolemys, who supported their new monarchy in Egypt after the death of Alexander by reinventing the Greek civic festival of Dionysus, with the monarch now at the center.

The basis of social and political life was the animal sacrifice, for which Prometheus supplies the most important foundation myth: he brought fire, therefore culture (in Greek thought), to mortals. Greeks and Romans slaughtered animals at altars outside the temple, with all citizens or relevant parties participating in the death and the consumption of meat. The offering to the god, combined with a communal act that reinforced equality (everyone in theory had an equal share, with special parts for the priests), provided an opportunity to eat meat. It is generally thought that in Greece little meat was eaten that had not been sacrificed. In Rome, so much meat appears to have been butchered in the imperial period that commercial slaughter may have predominated. Even in the Greek world, however, the sacred and commercial were not rigidly separated. Animals were bought for sacrifice, their skins were sold, and meat that was not distributed to participants at the temple could be taken to market and sold.

Sacrifice was a major part of many civic festivals, private associations, and family occasions. Offerings of one hundred cattle (known as a hecatomb) or more were made on major state occasions, while a piglet or lamb might be offered by a small community or family. Festivals were major occasions that shaped the civic year, and calendars specifying dates, types of offering, and the names of participants and beneficiaries survive on inscriptions and in Ovid's poem the *Fasti*.

This was the form of animal sacrifice to Olympian gods. For the gods of the underworld, the whole animal

was burned, and there was no consumption by human beings. Offerings of food were, however, made to the dead, and funeral feasts in their honor were eaten. The dead were also portrayed dining on couches, as they had done in life.

Cereals as well as animals played a major role in religion. They were the responsibility of the goddesses Demeter and Persephone in the Greek world, and of Ceres and other equivalents in Rome and Italy. Persephone in the related myth represented the corn. As she was abducted by Hades and later released to the upper world, so the grain is sown and sprouts in spring. The provision of grain was a major priority in all ancient states. Major festivals of Demeter were known in Sicily and Italy; there was also the Thesmophoria in many Greek cities, a festival for women only, which promoted the growth of corn and the conception of babies. (Sex and agriculture, human and plant reproduction, were often linked in Greek culture.) This festival was one of the few in the Greco-Roman world in which fasting was an

element prior to feasting (in the myth, Demeter brought famine to mortals when her daughter was lost). There are a few other parallels to the formal fasting found in Judaism or the fasting to near death found in the early Christian church. Demeter also presided at the Eleusinian Mysteries, where corn (grain) and the afterlife were central concerns. Legumes were also linked with the dead, both in Pythagorean belief and in such festivals as the Roman Lemuria, while mixtures of grains and beans represented the precivilized diet in such Greek festivals as the Anthesteria and Pyanopsia.

The other major god of food was Dionysus (or Bacchus), who presided over the growth of noncereal plants. His cult was closely linked with agriculture, and his most important plant was the vine. Wine was central to the libation, the pouring of liquids to a god, which was a widespread practice in the Mediterranean world from early times and accompanied sacrifice, prayer, and many social-religious acts. The consumption of wine was circumscribed by ritual in the "symposium," where gods received

drink-offerings of neat wine, and human drinking was in equal measures of wine and water, which were blended in the mixing bowl.

Animal sacrifice was complemented by nonblood sacrifices of cereals, honey, fruit, and vegetables, first fruits in particular. (The celebration of abundance, in art in particular, was often represented by the cornucopia.) Some cults specified nonblood offerings, particularly the Orphics and strict Pythagoreans, who abstained from the sacrifice and consumption of meat and fish. Less strict Pythagoreans allowed the sacrifice of some parts of some animals, since strict vegetarianism marked people as marginal and not participating in civic sacrifice.

New cults regularly arrived in the Greco-Roman world, such as the festival of Adonis, a Syrian god who died before maturity and was linked with the rapid growth of herbs and spices. Some foods rarely entered the sacred sphere. The most notable is fish. Greek and Roman authors noted the sacred fish of Syria and Egypt; in their own world, they often linked fish with luxury, since they belonged to the marketplace, and consumption was not regulated by religious constraints.

**ANIMALS: PRIMATE DIETS.** The daily food quest is generally the single most important activity for any animal. For this reason, natural selection should strongly favor any feature that enhances an animal's success at food acquisition. In essence, it has been suggested that different animal species can be viewed as "natural experiments" aimed at securing some portion of the always limited dietary resources available on the planet at any one time.

Humans are members of the Primate order and are placed in the suborder Anthropoidea, along with monkeys and apes. (When speaking of Primates as an order, the word is capitalized; when speaking of primates generally, the word is lowercased.) Because of our close relationship to other anthropoids, particularly the great apes (Pongidae), the dietary behavior of wild primates is of strong interest because it can provide clues about the types of dietary problems humans may have faced and resolved in their own evolution as well as insights into the probable dietary behavior of human ancestors and the nutritional composition of their wild foods.

#### The Role of Diet in Primate Evolution

Most primates are highly arboreal animals and carry out most activities in the canopy of tropical forest trees. Fossil evidence suggests that the earliest Primates evolved from small insectivores, initially attracted into the canopy by pollinating insects. Many morphological traits specifically associated with Primates, as, for example, keen stereoscopic vision, manipulative, grasping fingers, and a reduced dependence on the sense of smell seem to relate to selection for features associated with the efficient capture of items such as insects in an arboreal environment. However, because insects tend to be discretely distributed in the forest canopy and are also small in size, only small and relatively solitary primate foragers can be supported on such a diet.

Perhaps to circumvent these limitations, it would appear that natural selection favored a decided change in the dietary behavior of the ancestral primate, giving rise to the anthropoids. Though insects may be scarce, any animal in the tropical forest is continuously surrounded by potential plant foods. The evolution of anthropoids appears to have resulted from some early primate's ability to penetrate the arboreal plant food niche and then radiate (diversify) such that its descendants (monkeys and apes) came to dominate a strong subset of the most nutritious and energy-rich plant foods available in the forest canopy.

The idea that monkeys and apes are basically plant eaters may come as a surprise because, when we think of plant-eating animals, primates do not generally come to mind. Rather we think of cows and horses or rabbits and kangaroos. However, a wealth of field studies on many different species of wild primate show that all extant (living) monkeys and apes take by far the greatest percentage of the daily diet from plant foods, eating small to negligible amounts of animal matter. It is fair to say that primates are omnivores (taking the diet from both animal and plant foods) because most primates do eat some animal matter each day along with plant foods, but it is important to realize that most material entering the digestive tract of monkeys and apes is of plant rather than animal origin.

### Primates and Plant Foods

An orientation toward plant foods is characteristic of all anthropoids irrespective of body size. Many smaller monkeys take as much as 65 percent of the diet from concentrated plant foods such as gums and ripe fruits. For example, the smallest living monkey, the pygmy marmoset (*Cebuella pygmaea*, body weight less than 2 oz.) feeds primarily on calorie-rich plant gums and saps, supplemented with ripe fruits and insects. Larger monkeys as well as all apes take most of the diet from young leaves and fruits, supplementing these with seeds, flowers, and other plant parts, and often also eggs, insects, and small vertebrates. Orangutans and gorillas are estimated to take some 99 percent of their annual diet exclusively from plant foods—wild fruits, tender young leaves, piths, and the like—while for chimpanzees, this figure is some 94 percent. Though wild chimpanzees are known to hunt, kill, and eat small mammals, including monkeys, and also to eat termites and ants, such animal foods typically contribute only a small percentage to their annual diet, most of which is made up of ripe fruits. It is likely that many monkeys and apes would eat more animal foods if they could capture them more easily. Thus the low amount of meat in the average wild primate diet may relate more to the difficulties of getting animal food than to any aversion to eating it.

When we examine the digestive tracts of most plant-eating animals, animals such as deer, cows, or rabbits, we find that their digestive tracts show notable specializations to aid them in extracting sufficient nutrition from all of the plant foods they eat. With few exceptions, however, Primates do not show such dramatic digestive specializations—yet, Primates too are plant eaters. How are primates able to exploit plant foods successfully without the extensive digestive specializations we find in most other plant-eating animals?

### Primates Solve Dietary Problems with Their Heads

The answer is simple—primates tend to specialize on only the highest quality plant foods—foods that offer the most nutrition in exchange for the time and energy

invested in finding and eating them. Yet, very high-quality plant foods in the tropical canopy are bound to be less abundant than lower-quality plant foods. How then are primates able to afford the costs of their high selectivity?

To put it simply, primates use their heads. An unusually large complex brain relative to body size characterizes all primates. It is hypothesized that an unusually large brain was favored in primate evolution in part to aid in remembering the types and locations of higher quality plant foods as well as when such foods were ready to be harvested. Using their large brains, monkeys and apes can keep track of when particular important food trees are producing their nutritious new leaves or sugar-rich flowers or ripe fruits and can plan the most direct travel route to reach them at the opportune moment for harvest.

Thus primates use long-term memory and planning to lower the costs associated with seeking out the best foods in the forest canopy, and because the foods they eat are of relatively high quality, elaborate digestive specialization generally is not required to digest them efficiently. A few lineages of primates do show fairly elaborate digestive specializations. These lineages—as for example, the Colobinae or “leaf-eating” monkeys—have diets composed in large part of leaves, including many mature leaves that tend to be low in nutrients and hard to digest.

Anthropoids are also characterized by extreme sociality. Most monkeys and apes live in social groups composed of various adult females and males and their immature offspring. Each group occupies a particular area in the forest and, as a general rule, its descendants will continue to occupy more or less the same area generation after generation. For this reason, the social unit so characteristic of monkeys and apes can be regarded as a type of dietary adaptation for it enables the older individuals in the group to pass on important information to young animals about the types, locations, and seasonal patterning of the higher quality plant foods in their habitat—information essential for their survival.

### Each Primate Species Has a Particular Dietary Focus

Stressing that primates are largely plant-eaters is not to imply that all monkeys and apes have exactly the same diet, for they do not. Each primate species tends to have its own characteristic mix of plant (and animal) foods. In addition, each particular species typically specializes in only a certain subset of the higher-quality dietary resources in its environment. For example, the South American capuchin monkey, *Cebus apella*, has a high degree of manual dexterity and very powerful jaws. These features aid capuchins in cracking open the hard palm nuts that form an important part of their diet, which also includes ripe fruits, insects, and small vertebrates. Another monkey species often found living in the same

forests as *Cebus apella* is the spider monkey, *Ateles paniscus*. Spider monkeys are characterized by a low degree of manual dexterity and small teeth, which are useless for cracking hard-shelled palm nuts. But spider monkeys specialize in soft fruits and tender young leaves, not hard palm nuts. They are also much bigger than capuchin monkeys, and if the supply of softer fruits is limited, they can chase capuchin monkeys out of fruiting trees and monopolize the fruit crop for themselves.

### The Role of Diet in Human Evolution

As discussed, the closest living relatives of humans, the great apes, all eat plant-based diets. The common ancestor giving rise both to apes and humans is likewise believed to have been primarily plant-eating. All humans and apes have the same basic digestive tract—a simple acid stomach, a small intestine, a tiny cecum, and a sacculated (folded) large intestine (or colon), though the human small intestine is longer and the human colon smaller than is the case for apes. Humans and apes also show the same pattern of food digestion, indicating that, biologically, in terms of gut form and function, humans have departed little from the ancestral condition. But, unlike apes, humans eat a wide range of different foods and have many different types of diets. What factors may have contributed to this difference between humans and apes?

Some 3 million years ago, before the first evidence of human beings, we know that climatic changes caused the vegetation in many areas of Africa to shift from tropical forest to more open savanna vegetation. This produced notable changes in the types of plant foods available in these environments. In particular, finding sufficient high-quality plant foods throughout the year probably would have been difficult for a large apelike primate such as those we envision as prehuman ancestors. One solution to this problem would be to try and find some other source of high-quality food. Animal foods are such a source: they are very high quality and, because of the huge herds of grazing and browsing animals in the African savanna, animal foods are far more abundant than is the case in the tropical forest canopy.

The association of stone tools with the earliest fossil evidence for human beings (genus *Homo*, species *Homo habilis*) suggests that early humans began to include animal as well as plant foods in the diet. Rather than just being an occasional food, as is the case for chimpanzees or other apes, meat and other animal products (tongue, bone marrow, brains, fat) appear to have become an integral part of the daily human diet. Initially, the earliest humans may have lived as scavengers and relied on meat from kills abandoned by carnivores. But increasing numbers of stone tools and processed mammal bones in the archaeological record suggest that humans gradually turned to the hunting of larger animals.

Animal protein is of high quality and easy for humans to digest. It also is a rich source of many essential

vitamins and minerals. In addition, and most importantly, animal foods are volumetrically concentrated relative to plant foods and thus take up much less space in the feeder's gut. By eating some meat each day and combining this animal food with energy-rich plant foods, humans evolved as large-brained, active, and social hunter-gatherers. The fossil record shows that the human brain increased substantially over the course of human evolution. It would seem that, initially, the earliest human ancestors were somehow able to include a modest amount of animal food in the diet on a routine basis along with their usual plant foods. But these animal foods provided much high-quality nutrition and also freed up space in the gut for energy-rich plant foods, thus improving the feeder's diet in terms of both nutrients and energy. This energy was required to fuel the increasingly large human brain, which requires glucose as fuel. More astute individuals doubtless were more proficient at securing animal foods as well as energy-rich plant foods and they passed these mental abilities on to their descendants. Over time, this feedback process resulted in the gradual expansion of the human brain.

### Humans as Cultural Omnivores

The evolution of humans actually follows the common primate trajectory—that is, using brain power to resolve many important dietary problems. Morphologically, humans lack the huge jaws, massive teeth, and sharp claws of true carnivores. But their increasingly large and complex brains permitted early humans to substitute technology for carnivore teeth and claws and use tools and creative intellectual solutions to capture and prepare their animal and plant foods for consumption.

In addition, early humans developed a unique form of food acquisition characterized by a division of labor. Typically, male members of the social unit sought animal prey while female members sought out higher-quality plant foods. Then all of the foods collected each day were shared with all members of the social unit, giving each person a good mix of all of the different nutrients required to remain in good health. By entering the adaptive zone of culture—cultural behavior made possible by virtue of the unusually large and complex human brain—humans gradually developed the capacity to exploit dietary resources of all types in ways not possible for any other animal. The success of this uniquely human form of dietary behavior is manifested by the fact that over time, by using their wits to devise successful diets, humans have been able to colonize almost every environment on earth. As long as all of the nutrients humans require are present in their foods, humans can thrive on an amazing variety of different diets.

**ANOREXIA, BULIMIA.** Anorexia nervosa (AN), bulimia nervosa (BN), and Eating Disorder Not Otherwise Specified (EDNOS) are three of a spectrum of conditions, commonly known as eating disorders, associated with abnormal eating patterns and a desire to be thin. The abnormal eating patterns in these eating disorders include restriction of food intake, binge eating, and purging with laxatives or by self-induced vomiting. Persons with each of these disorders may go through periods of restriction, binge eating with purging, and binge eating without purging.

The term "eating disorders" for these conditions is both correct and misleading. These disorders center around issues of eating, or, to be more exact, food consumption, and certainly can be qualified as disorders, but more than eating is disordered in these conditions: they are associated with a complex of psychological, physiological, neurological, and hormonal changes, which may be due to the disease itself, or to the changes in weight

associated with inappropriate food intakes and energy outputs, or both together.

The notion that thinness is desirable, particularly in women, and that one can never be "too rich or too thin," now permeates Western societies and is becoming increasingly common elsewhere. Teenagers, who are normally preoccupied with body image, and prone to be concerned about gaining weight, may incorrectly perceive themselves as being overweight, because puberty coincides with marked changes in body shape and, for girls, increased body fat content with fat deposition in the hips. Surveys in Western countries have shown that at any one time, up to two-thirds of female high school students either are on a weight loss diet or were on one in the recent past. In the United States, eating disorders seem to be less common among African-American and Asian females than among white females, equally common among Latina females, and surprisingly common among Native Americans. Japan seems to be the country with the highest prevalence of eating disorders. Other countries seem to be catching up, wherever there is access to food and to Western modes of behavior, as exemplified in the media.

Psychological conditions associated with eating disorders include depression, affecting 50–75 percent of people with eating problems; bipolar disorder (manic-depressive illness, 4–15 percent); obsessive-compulsive disorder, affecting as many as 25 percent of people with AN, fewer in those with BN; substance abuse, in up to one-third of patients with BN; and personality disorders, particularly avoidant, in other words, mistrusting, personality. Twenty to fifty percent of patients with BN (and to a lesser extent patients with AN and other eating disorders) have experienced sexual abuse.

A syndrome called "the female athlete triad"—consisting of disordered eating, amenorrhea (disruption of menses), and osteoporosis—is becoming more common as athletic prowess has become desirable for women and as women have better access to athletic facilities in the United States because of Title IX of the Educational Assistance Act (1974). Patients with Type I diabetes mellitus appear to be more prone than the general population to eating disorders, and may use underdosing with insulin to lose weight—when they do not take enough insulin, the body fails to use and store the calories they eat and relies on breakdown of fat and muscle for fuel.

Patients with eating disorders may become parents, may have difficulties nurturing their own children, and may transmit disordered attitudes toward eating to their children. The health care team should take these difficulties into account in treatment plans for both parent and child.

## Anorexia Nervosa

Anorexia nervosa (AN) represents an extreme version of the desire for thinness. The term "anorexia" is a mis-

nomer, for a person with this condition does have an appetite, but restricts food intake and denies the desire to eat with the apparent aim of having precise control over body shape and weight. Perhaps the German *Pubertätmagersucht*—"seeking thinness at puberty"—is a more accurate term, although the disorder has antecedents in childhood and continues into adulthood.

**Epidemiology.** In the United States, nearly 90 percent of patients with overt, clinically recognized AN are females between the ages of twelve and twenty-three, although younger and older patients as well as males may also develop the disease. The prevalence of AN appeared to rise during the twentieth century, with a lifetime risk among women of 0.5 percent to 3.7 percent and a male to female prevalence ratio between 1 to 6 and 1 to 10. The prevalence among young adolescent males is higher, perhaps reflecting a secular trend or an increasing emphasis on male appearance and "fitness."

The only groups among whom the disease has been recognized are groups who have easy access to food, and among whom being thin is a socially desirable state. However, conditions clinically indistinguishable from AN have existed in Western cultures prior to the twentieth century, particularly during the late Middle Ages and Renaissance, when they were associated with religious asceticism—the professed goal was to demonstrate the person's ability to deny the needs and pleasures of the flesh, rather than to be thin for social acceptance. Similar conditions associated with religious practices also occur in other cultures.

**Etiology.** Scientific opinion concerning the etiology of AN has vacillated between a biological and genetic explanation and a sociopsychological one. The patient's complaints lie in the psychological realm, while the disease presents features that point to biological and genetic components. There is a significantly higher concordance of anorexia nervosa among monozygotic twins (identical, that is, having the same genes) than among dizygotic twins (fraternal, that is, genetically only as close as a non-twin sibling). Family members have a higher than expected prevalence of other affective (emotional) and addictive disorders.

A host of neurohormonal changes appear once starvation has set in, but it is unclear which of these changes are causal, which are due to progression of the disease, and which are due to semistarvation. A reasonable explanation for the condition is that the person first restrains eating or performs excessive exercise for psychosocial reasons, and then develops a biologically driven self-perpetuating condition.

**Development, signs, symptoms and biological findings.** Anorexia nervosa develops in three phases, often preceded by picky eating and digestive problems in childhood. In Phase I the patient develops an increased consciousness about physical appearance, coupled with a

### ***Diagnostic Criteria for Anorexia Nervosa (Diagnosis Number 307.1)***

- A. Refusal to maintain body weight at or above a minimally normal weight for age and height (e.g., weight loss leading to maintenance of body weight less than 85 percent of that expected; or failure to make expected weight gain during period of growth, leading to body weight less than 85 percent of that expected).
- B. Intense fear of gaining weight or becoming fat, even though underweight.
- C. Disturbance in the way in which one's body weight or shape is experienced, undue influence of body weight or shape on self-evaluation, or denial of the seriousness of the current low body weight.
- D. In postmenarcheal females, amenorrhea, i.e., the absence of at least three consecutive menstrual cycles. (A woman is considered to have amenorrhea if her periods occur only following hormone, e.g., estrogen, administration.)

Specify type:

Restricting Type: during the current episode of anorexia nervosa, the person has not regularly engaged in binge-eating or purging behavior (i.e., self-induced vomiting or the misuse of laxatives, diuretics, or enemas).

Binge-Eating/Purging Type: during the current episode of anorexia nervosa, the person has regularly engaged in binge-eating or purging behavior (i.e., self-induced vomiting or the misuse of laxatives, diuretics, or enemas).

SOURCE: American Psychiatric Association, *Diagnostic and Statistical Manual of Mental Disorders*, 4th ed. Washington, D.C.: American Psychiatric Association, 1994.

loss of self-esteem, and begins dieting and exercising to lose weight. While these beliefs and behaviors have become increasingly the norm among adolescent women in developed countries, in certain people it progresses to Phase II.

During Phase II (frank AN) the person develops an "anorectic attitude": an unreasonable fear of eating coupled with pride in the ability to lose weight. Restriction of food intake begins with "fattening," "dangerous" foods such as carbohydrates and fats, while other foods, particularly vegetables, are viewed as "safe." In an effort to rationalize their restrictions, patients may develop a sophisticated fund of nutritional knowledge. They may delude parents or other caretakers into believing that they are eating when in fact food may be hidden or vomited

up. Patients may also become obsessed with preparing foods, which they then refuse to eat. Some patients may have episodes of binge eating with or without purging in addition to restriction. Patients with this form of anorexia nervosa are more likely to be depressed, suicidal, and self-harming.

Patients may persist in the belief that they are eating a lot when in fact they eat very little. Sensations of hunger and satiety are impaired, with the result that these two states become confused. Further, delayed gastric emptying due to developing malnutrition may contribute to the perception of fullness after consumption of only small amounts of food. Eventually the person may reject all or nearly all foods.

The “anorectic attitude” may be self-amplifying, in that starvation itself may lead to abnormal attitudes towards food. Semistarved persons who are otherwise in good health also develop an obsession with food, linger for hours over a meal, and may feel that once they start eating, they will not be able to stop. For persons with AN, the thought that they may not be able to stop may be a terrifying prospect, confirming their worst fears about their inability to control their appetite.

The types of food that a person with AN likes appear to be normal when ascertained by questionnaire; however, a dislike for high-fat and low-carbohydrate foods is revealed. Taste testing suggests that persons with AN have an abnormally high preference for highly sweet tastes, coupled with a dislike of fatty foods. In this phase, the person may use laxatives and enemas, in the belief that these procedures will prevent absorption of ingested food, and also because anorexics may judge themselves to be constipated since the severely reduced food intake leads to formation of smaller than normal amounts of feces. Laxatives and starvation-induced changes in gut motility lead to both constipation and complaints of abdominal pain. Patients may abuse diuretics in an attempt to lose weight, although their effect is confined to water weight loss.

Patients may participate in extreme physical activity, preferably carried out alone, although it may be expressed in organized group activities such as ballet or athletic performance. This physical hyperactivity is in direct contrast to the inactivity seen in starving subjects without AN.

Depression, anxiety, obsessional traits, perfectionism, and rigidity in thinking are all found in patients in Phase II of AN. The states are often associated with social isolation.

During Phase II, nutritional status may deteriorate steadily, and if untreated, patients may not enter the recovery phase, Phase III. Death may occur from cardiovascular collapse due to starvation and electrolyte imbalance, or due to too rapid refeeding, as well as suicide. As many as 5 percent of patients may die of AN in the acute phase, and 20 percent on long-term follow-up—the highest mortality rate for a psychiatric condition.

Phase III of this disease, which is attained only with difficulty, and in some cases not at all, is the acknowledgment by the patients that they have starved themselves, and need treatment, coupled with success at alleviating the signs and symptoms of the disease.

**Management.** The management of anorexia nervosa is complex, requiring a concerted effort on the part of the health care team, including physician, nurse, nutritionist, social worker, and psychologist, as well as the patient and his or her family. Because patients are capable of maintaining a state of denial, it is very difficult to engage the patient into the care process. Often the patient has to be in a state of collapse before intervention is even tolerated. Indications for hospitalization are weight loss below 40 percent of normal weight; orthostatic hypotension (low blood pressure when standing); electrolyte (sodium, potassium) imbalance; dehydration; hypoglycemia (low blood sugar); infection; and marked family disturbance.

Treatment involves refeeding and psychological rehabilitation. Refeeding is critical for all patients whose weight is 85 percent or less of that expected. Depending on the severity of the patient’s malnutrition, feeding may occur in the hospital, in a clinic setting, or at home. The patient should be hospitalized well before collapse is imminent. Feeding may be oral, naso-gastric, or via intravenous lines. Oral feeding is preferred but some patients may only permit refeeding if it is through a naso-gastric tube, and thus beyond their control. Intravenous feedings may be required if cardiovascular collapse is imminent. No special diets are needed, although concentrated foods may be useful in attaining adequate caloric intakes, and vitamin and mineral supplements are required. Refeeding must be slow, and performed under close medical monitoring, lest the patient develop edema and increased circulating blood volume, which can lead to electrolyte imbalances, anemia, and cardiovascular collapse. Other fatal complications of rapid refeeding include acute stomach or large bowel dilatation. Treatment protocols may also include restriction of exercise, in order to prevent the patient from exercising away the calories. Some patients are adept at finding ways to increase physical activity in the face of exercise restriction, and some patients may become severely agitated when denied the right to exercise.

Psychological treatment varies by health care team and may combine individual, family, and group therapy. Drug therapy may be used, particularly selective serotonin reuptake inhibitors (SSRIs), especially in patients who have regained weight but still are depressed or have obsessive-compulsive symptoms.

The ideal of clinical improvement consists of a return to 90 percent of normal weight, the resumption or initiation of menses in women, normalization of eating patterns, as well as the development of a mature, self-confident outlook, with a normal body image. Few patients attain this ideal. However, the short-term prog-

nosis with respect to weight gain, return of menses, and improvement in outlook is usually good, although the food obsession and inability to control appetite may persist for weeks to months after the patient has regained an adequate amount of weight.

Unfortunately, the long-term prognosis is not so favorable: On the average, about 40 percent of patients recover more or less completely, 27 percent have ongoing endocrine abnormalities or are mildly underweight, 29 percent have a serious recurrence of the disease within a four-year period, and up to 5 percent succeed in starving themselves to death. Those who are over twenty, have prolonged illness, are depressed, have a family history of mental disturbance, have poor family relationships, who use purgatives and diuretics and who follow binges with vomiting have the worst prognosis.

### **Bulimia Nervosa**

People with bulimia nervosa (BN) have recurring irresistible urges to consume extremely large amounts of food at one sitting (binge). The binge leads to acute feelings of gastric distension, and to sharpening of the fear of becoming fat. To relieve both problems, patients may then proceed to self-induce vomiting or purging. Persons with this condition report a sense of "cleaning out" with vomiting and purging, which may positively reinforce these behaviors. Note that binging without purging comes under the rubric of Eating Disorders Not Otherwise Specified (EDNOS), according to the Diagnostic and Statistical Manual of Mental Disorders, 4th ed. (DSM-IV), and is described below.

Precipitants of a binge include hunger, being alone, feelings of anxiety, frustration, and worthlessness, and problems with a significant other.

**Epidemiology.** Like AN, BN primarily afflicts young females from food-rich backgrounds. Its prevalence is unknown because only the most severely affected come to health care. Estimates of the disorder vary from 2.5 to 20 percent of women and 1 to 5 percent of men from the ages of eighteen to twenty-one.

**Etiology.** The etiology of BN remains unknown. Causes may include a biological predisposition to obesity, depression, and metabolic disturbances (in particular neurohormonal abnormalities, such as abnormalities in the release of gut hormones after eating), coupled with a socially determined desire for thinness, and with bingeing and purging as a group activity, a phenomenon which is becoming increasingly common among women living together, for example in a sorority, or men as part of a team, for example wrestlers.

Families of BN patients have a high prevalence of disorders such as major depression, irritable bowel syndrome, obsessive-compulsive disorder, attention deficit disorder with hyperactivity, and migraine, all of which have been linked to abnormalities in the function of neu-

### **Diagnostic Criteria for Bulimia Nervosa (Diagnosis Number 307.51)**

- A. Recurrent episodes of binge eating. An episode of binge eating is characterized by both of the following:
  - (1) eating, in a discrete period of time (e.g., within any 2-hour period) an amount of food that is definitely larger than most people would eat during a similar period of time and under similar circumstances
  - (2) a sense of lack of control over eating during the episode (e.g., a feeling that one cannot stop eating or control what or how much one is eating)
- B. Recurrent inappropriate compensatory behavior in order to prevent weight gain, such as self-induced vomiting; misuse of laxatives, diuretics, enemas, or other medications; fasting; or excessive exercise.
- C. The binge eating and inappropriate compensatory behaviors both occur, on average, at least twice a week for three months.
- D. Self-evaluation is unduly influenced by body shape and weight.
- E. The disturbance does not occur exclusively during episodes of anorexia nervosa.

Specify type:

Purging Type: during the current episode of bulimia nervosa, the person has regularly engaged in self-induced vomiting or the misuse of laxatives, diuretics, or enemas.

Non-Purging Types: during the current episode of bulimia nervosa, the person has used other inappropriate compensatory behaviors, such as fasting or excessive exercise, but has not regularly engaged in self-induced vomiting or the misuse of laxatives, diuretics, or enemas.

rotransmitters (chemicals such as norepinephrine and serotonin responsible for sending messages from one nerve cell to the next) in the brain. Levels of monoamine oxidase (MAO, an enzyme responsible for degrading norepinephrine and serotonin) in the blood cell clotting fragments called platelets are lower than normal in a person with BN. Low activity of MAO has been associated with impulsiveness, intolerance of boredom and monotony, and sensation seeking, also commonly seen in bulimic individuals. SSRIs, specifically fluoxetine, which increase

TABLE 1

**Physical signs and symptoms associated with anorexia nervosa and bulimia nervosa**

	<b>Anorexia nervosa</b>	<b>Bulimia nervosa</b>
Body weight	Usually below normal	May be below normal, normal, or above normal
Skin and hair	Dry skin; lanugo (soft down-like hair overgrown on limbs, nape of neck, and cheeks); yellowing of skin (but not whites of eyes) due to excessive consumption of carrots and other carotene containing vegetables	Scratches on the dorsum of the hand due to rubbing of the hand against the upper teeth during self-induced vomiting
Teeth	Increased caries due to acid erosion, if patient vomits frequently	Cariou due to acid erosion, if patient vomits frequently
Water and electrolytes	Low blood potassium, due to vomiting; low blood sodium due to use of laxatives	Low blood potassium due to frequent vomiting
Bones	Osteoporosis leading to irreversible vertebral collapse, due to lack of estrogen, and to reduced consumption and to malabsorption of minerals and fat soluble vitamins	Incidence of osteoporosis variable
Amenorrhea	Characteristic	Variable
Brain	Brain damage in long-term disease, which may be irreversible	Unknown
Gastro-intestinal tract	Slow gastric emptying and slow intestinal transit time, due to starvation	An enlarged stomach with stomach cramping, leading to digestive difficulties; esophageal irritation, due to regurgitation of stomach acid; dysmotility of the esophagus (poor coordination of esophageal movement); slow stomach emptying; injury to the nerves in the gut wall, leading to permanent loss of bowel reactivity; constipation and diarrhea.
Metabolic rate	Reduced	Mildly reduced
Body temperature	Reduced, with difficulty maintaining a steady body temperature in cold or warm conditions; an occasional patient has an elevated metabolic rate	Variable
Cardiovascular system	Hypotension (abnormally low blood pressure); bradycardia (slow heart rate); decreased heart size and cardiac output	Variable, depending on body weight; if body weight is low, the signs are similar to those seen in Anorexia nervosa.
Blood	Anemia and leukopenia (low white blood cell count) due to inadequate mineral intake and to starvation	Anemia, due to frequent small upper gastrointestinal tract bleeds, leading to iron loss
Causes of death	Cardiovascular collapse, suicide	Cardiovascular collapse, suicide

responsiveness to endogenous serotonin, are moderately effective in treatment of BN. Abnormalities in other hormones and neurotransmitters, including cholecystokinin (CKK), which is released in response to fat in the intestine and depresses appetite, neuropeptide YY, which is involved in activating appetite, and leptin, are under investigation.

***Development, diagnosis, and clinical manifestations.***

The phases of development of BN are far less clear than those of AN, though, as children, patients with this condition may have had pica (the consumption of nonfood items such as dirt or paint chips), and may have suffered through mealtimes in which there was a great deal of commotion and distress. Some bulimics have been severely abused physically, sexually, or both and may show signs and symptoms of post-traumatic stress disorder, including multiple personality disorder.

It is difficult to determine when bingeing becomes an overt pathological state. Binge episodes may vary from several times daily to once a month or less, and 20 per-

cent of female college students are estimated to have participated at least once in a binge-purge episode.

A binge-purge episode starts with a craving for high-calorie food, usually those high in carbohydrates and fat but low in protein, particularly junk food, which does not have to be cooked. The food is obtained and consumed at one sitting. Thus, a patient may consume a box of cookies, a bag of doughnuts, and a half-gallon of ice cream in a single binge. The binge may then be followed by self-induced vomiting, and/or laxative use. Binges and purges most often occur in private, although there is an increase in group binge-purge episodes among young people who live in communal settings, for example in boarding school or in college. The frequency of episodes increases with increasing stress. Some patients may fast between episodes of bingeing, and may in fact have the binge-eating/purging form of AN. Other patients may binge without purging.

In BN, eating patterns outside a binge-purge episode are usually characterized by a degree of restrained eat-

ing. Nevertheless, when bulimics perceive that they have “violated” the restraint, that is, eaten more than “allowed,” they will eat more than a normal person in a test meal situation. Increased postmeal hunger is also experienced by individuals with BN. The restrained eating may therefore be the result of conscious attempts to compensate for the inability to feel satiety, and may be a mechanism for maintaining normal weight in the face of episodes of great hunger and craving. Patients have larger than normal stomachs, which results in both slower than normal stomach emptying and failure to sense fullness, due to excessive relaxation of the stomach, and lower than normal levels of the hormone cholecystokinin (CCK) after a meal. CCK is produced in the intestinal tract in response to fatty food, and signals to the brain that the person has eaten enough. As a result of these changes, the person may fail to be aware of satiety. It may be that once binge-purge episodes have begun, these anatomical and physiological changes will amplify the perceived need to binge, and the consequent need to purge.

In taste tests, persons with BN have a higher than normal preference for very sweet and very fatty foods. Normally, the more a person eats of a sweet food at a single sitting, the less pleasant it becomes. Bulimics may not experience this decrease in pleasantness, as a result of which they may be able to eat large amounts of highly sweet food.

The hypothalamus normally senses when blood glucose levels have risen following food ingestion, which also contributes to the feeling of satiety. Persons with BN appear to have mild insulin resistance, which may prevent their hypothalamus from sensing that rise in blood glucose levels.

Persons with BN are less likely than persons with AN to have a distorted body image, though persons with BN do express an overvaluation of thinness and a fear of becoming overweight. A person with BN may be depressed and agitated, but, unlike a person with AN, usually does not participate compulsively in physical activity.

The most striking complaints and physical and biochemical findings regarding BN are related to the frequent vomiting (Table 1). The ability to taste with the palate may be destroyed due to the stomach acid, although taste by the tongue is little affected. Whether these taste changes contribute to bingeing is unknown.

**Management.** Bulimia nervosa requires long-term, continuous, nonjudgmental psychological management, nutritional counseling, and rehabilitation, and may include medications, particularly SSRIs. Cognitive behavioral therapy approaches that redirect the person’s attention away from food and eating, and which address the person’s other psychological problems, are the most successful. Patients may have other conditions, such as drug abuse or personality disorders, which need to be addressed before the eating disorder. Both depressed and nondepressed patients with BN may benefit from med-

### ***Diagnostic Criteria for Eating Disorder Not Otherwise Specified (Diagnosis Number 307.50)***

The Eating Disorder Not Otherwise Specified category is for disorders of eating that do not meet the criteria for any specific Eating Disorder. Examples include

1. For females, all of the criteria for anorexia nervosa are met except that the individual has regular menses.
2. All of the criteria for anorexia nervosa are met except that, despite significant weight loss, the individual’s current weight is in the normal range.
3. All of the criteria for bulimia nervosa are met except that the binge eating and inappropriate compensatory mechanisms occur at a frequency of less than twice a week or for a duration of less than 3 months.
4. The regular use of inappropriate compensatory behavior by an individual of normal body weight after eating small amounts of food (e.g., self-induced vomiting after the consumption of two cookies).
5. Repeatedly chewing and spitting out, but not swallowing, large amounts of food.
6. Binge-eating disorder: recurrent episodes of binge eating in the absence of the regular use of inappropriate compensatory behaviors characteristic of bulimia nervosa.

ications such as SSRIs. These drugs may help with interpersonal functioning, mood, and anxiety symptoms.

### **Eating Disorder Not Otherwise Specified**

Eating Disorder Not Otherwise Specified (EDNOS) is the term applied to conditions that have some characteristics of the classic eating disorders AN and BN, but which do not meet all the diagnostic criteria outlined in the DSM-IV. Multiple combinations of signs and symptoms are possible, as noted in Table 1. Persons who abuse weight-reduction medications and other regimens, and who are trying to lose large amounts of weight for reasons of beauty rather than health, as well as persons with binge-eating disorder, also fall under this rubric, as do people who use disordered eating behaviors in an attempt to correct the size of what they perceive as abnormally large (or abnormally small) body parts.

Binge-eating disorder is characterized by binges that are not followed by efforts to get rid of the extra calories. It is estimated that about 2 percent of the general population suffers from this condition, with a male to fe-

Sophie Sukup's *Iss dich schlank!* (Eat Yourself Thin!), published in Stuttgart, Germany, in 1927, promised overweight readers that they could get immediate results by eating the fat away. The cover design of the book makes it clear that the new ideal physique is no longer that of the Rubenesque maiden of pre-1918 Germany. ROUGHWOOD COLLECTION.

male ratio of 1 to 3, in contrast with frank bulimia nervosa, where the proportion is closer to 1 in 6. Because people who have this disorder do not vomit or purge, they are often obese; they compose about a third of the patients visiting weight reduction clinics. They also may have body image dissatisfaction, low self-esteem, and depression. Active psychotherapy can reduce binge frequency, but once therapy is discontinued, relapse rates are high, and weight lost due to the decrease in binge frequency is often readily regained. Approaches that emphasize self-acceptance, improvement of body image, and better overall health, rather than focusing on weight loss, appear to have the best long-term success rate. It is likely that similar approaches may be effective for people who abuse weight-loss regimens.

**ANTHROPOLOGY AND FOOD.** What distinguishes the anthropological study of food from that of other disciplines is its focus on food within a cultural and often cross-cultural context. Anthropologists study humans and human culture across space and evolutionary time; this includes the study of their own culture and social institutions. Subfields of the anthropological study of food include cultural, linguistic, biological, and archaeological anthropology. Research in nutritional anthropology cuts across these subfields. Food requires hunting, gathering, growing, storage, distribution, preparation, display, serving, and disposal, all of which are social activities. Topics for the anthropological study of food within a cultural system include economy, inequality, gender, status, hunter-gatherers, and food as a symbol.

Of basic interest to archaeologists is the diet or subsistence pattern of the peoples they study. Since seasonal patterns of movement are often linked to subsistence regimes, archaeologists frequently study the overall settlement-subsistence pattern. Other major topics of study related to food are the origins of agriculture, the process of plant and animal domestication, and the study of foodways (food in a social and cultural setting). With the help of interdisciplinary teams of specialists, archaeologists examine a variety of evidence such as animal bones (faunal analysis or zooarchaeology), plant remains (paleoethnobotany or archaeobotany), human bones (osteology), residues (chemistry), and the settlement system. Faunal and paleoethnobotanical analyses are able to determine diet (which animals and plants were eaten) as well as hunting, gathering, butchering, and preparation techniques, the identity of preferred or high-status foods, the seasonality of site occupation and diet items, and whether the animals/plants were domesticated. The phrase "You are what you eat" is true in that what you eat forms the

## ARCHAEOLOGICAL FOODWAYS

Foodways is a subdiscipline of cultural anthropology that studies food in its social and cultural setting. Foodways studies were pioneered in the 1990s by archaeologists who study hierarchical, stratified societies in the southeastern United States. A foodways approach combines studies of food remains, the ceramic vessels used to prepare and serve food, and other aspects of the food system with settlement patterns to answer questions about cultural change and the production, storage, distribution, preparation, and serving of food within social contexts. Two examples illustrate the cultural richness that such research may provide. In her study of the people who lived in the central Mississippi River Valley between 500 and 1100 C.E., Sissel Johannessen examined multiple lines of evidence to understand the relationship between shifts in diet and social changes. Her work combines summaries of internal community patterning, food storage facilities, paleoethnobotanical remains, and ratios of different types of ceramic vessels and sets them within the six-hundred-year period during which this farming society adopted maize agriculture. Johannessen documented how change in diet, accompanied by changes in food production, distribution, storage, and consumption, reflected a basic shift in social interaction and people's perception of their place in the world. They went from living as isolated families in the sixth century to group solidarity and affiliation with mound centers. As the locus of power shifted from household to center, food storage shifted from household pits to above-ground granaries, and greater variation arose in the ways food was cooked and served.

Another example is the study by Paul D. Welch and C. Margaret Scarry, who used a foodways approach to examine the intricacies of the social relationships within a chiefdom in the southeastern United States dating between 1050 and 1550 C.E. The ratios of food processing by-products (maize cobs and nutshells) and food consumption evidence (maize kernels) differ between low-status (farmstead) and high-status (civic/ceremonial mound center) locations, as do the types and cuts of meat and the ratios of cooking to storage or serving vessels. Furthermore, analysis of the ceramic vessel ratios from the various locations allowed distinction between types of high-status activities.

### Linguistic Anthropology

Linguistic anthropologists study human perception and communication, finding a close connection between how

The !Kung hunter Gumtsa digs up a plant for food. The !Kung peoples live in the Ngamiland District of Botswana. Their primitive lifestyle and simple foodways are of great interest to anthropologists. © PETER JOHNSON/CORBIS.

bones and organs in your body, leaving behind chemical signatures. Human bones reflect the general health and nutrition of the individual, and may be chemically analyzed to reveal diet through isotopic (heavy element) or chemical signatures.

### Biological Anthropology

Topics in biological anthropology range from biological and nutritional questions about humans and primates (e.g., questions of nutrition, health, and evolution of human and primate physiology and diet) to cultural practices and choices that affect biology and nutrition (e.g., dietary strategies and food selection choices). Cross-disciplinary themes include the process of human adaptation, population variation, and health. In many societies, medicine is not distinguished from food. Human digestive systems, the substances upon which humans feed, and medicinal natural substances are closely intertwined and are the result of a co-evolution.

These prehistoric flint tools were used for hunting and preparing food. © MAURICE NIMMO; FRANK LANE PICTURE AGENCY/CORBIS.

people perceive their world and the structure of their language. The field of folk taxonomy recognizes regularities in how humans perceive and categorize their natural world. A society's closeness to nature and sources of food will be reflected in how finely they are able to categorize plants and animals, and more salient plants and animals will be marked linguistically. Linguists who study folk taxonomy usually consider themselves ethnobotanists or ethnobiologists (see below).

### Cultural Anthropology

Cultural anthropologists pioneered the method of ethnographic data collection wherein the anthropologist lives among and participates in the daily life of the native culture over a period of months or years. Ethnographers attempt to situate the study of food within a community or culture, seeking to explain the interrelation between food systems and human behavior. Frameworks for the study of food include but are not limited to economy, political economy, cultural ecology, inequality, gender, ethnicity, households, policy formulation, biodiversity, hunter-gatherers, urbanization, and food as symbol. Cross-cultural research compares food and food systems in different cultures, most recently through multisited studies.

### Ethnobotany and Ethnobiology

Ethnobotany (study of the relationships between plants and peoples) and ethnobiology (study of the relationships between living organisms and humans) draw on the resources of each of the subdisciplines of anthropology as

well as from other fields such as chemistry, botany, pharmacology, zoology, entomology, engineering, and so on. A major concern of these disciplines is intellectual property rights—who should be compensated, and how they should be compensated, for sharing their traditional knowledge about plants and animals or for sharing the results of breeding plants or animals.

**ANTIOXIDANTS.** Antioxidants are specific organic compounds that are active in the prevention of very rapid harmful chemical chain reactions with oxygen or nitric oxide, that is, oxidation reactions. In the body, oxidation reactions generally involve highly reactive molecules called free radicals. Free radicals reside primarily in the mitochondria of cells. When free radicals are released from the mitochondria in numbers sufficient to overwhelm the protective biochemical systems of the body, they become a threat to some cellular structures such as lipids, proteins, carbohydrates, and nucleic acids in cell membranes. Compromised cellular structure alters cellular function, and may lead to the initiation of the disease process. In severe oxidative stress, cell death may occur. Antioxidants react with the free radicals before they are able to react with other molecules, thus providing protection from oxidation reactions (Cross et al.).

### Chemistry 101: How and Why Cells and Other Molecules Interact

The human body is made up of many different types of cells that are composed of multiple diverse types of molecules. Molecules are put together in such a way that one or more atoms of one or more elements are joined by chemical bonds. Atoms have a nucleus of neutrons and protons which is surrounded by electrons. It is the number of protons (positively charged particles) in the nucleus of the atom that determines the number of orbiting electrons (negatively charged particles). Electrons are involved in chemical reactions and are the substances that bond atoms together to form molecules. Electrons orbit the atom in one or more of the atom's shells. The innermost shell is full when it has two electrons. When the

first shell is full, electrons begin to fill the second shell. When the second shell has eight electrons, it is full, and electrons begin to fill the third shell, and so on. The electrons surrounding antioxidants react with the electrons surrounding free radicals, causing them to become much less reactive. Antioxidants may be more effective when one antioxidant is used in combination with another. This synergistic relationship between several antioxidants occurs when, for example, vitamin E donates an electron from its outer shell to a free radical and vitamin C donates an electron to vitamin E, maintaining the ability of vitamin E to continue donating electrons to free radicals. Vitamin C may then receive an electron from glutathione that would enable vitamin C to remain active as an antioxidant. Therefore in this type of situation, an attack on membranes by a free radical results in the participation of three different antioxidants.

### In What Forms Are Antioxidants Found and How Are They Metabolized?

Antioxidants are found in many forms. The principal vitamins with antioxidant properties are vitamins E and C, and beta-carotene. Vitamin E (*d*-alpha tocopherol) is a fat-soluble antioxidant, which means it is stored in body fat and works within the lipid portion of cell membranes to provide an alternative binding site for free radicals, preventing the oxidation of polyunsaturated fatty acids (Chow). Vitamin E is a family of eight compounds synthesized by plants in nature: four tocopherols (alpha, beta, gamma, delta) and four tocotrienols (alpha, beta, gamma, delta). Each has different levels of bioactivity in the body over quite a wide range, but generally speaking, alpha-tocopherol has greater bioactivity than beta-tocopherol, which has greater bioactivity than gamma-tocopherol, which has greater bioactivity than delta-tocopherol. Only alpha-tocotrienol has bioactivity of any significant amount, which is slightly less than that of beta-tocopherol. Digestion and absorption of vitamin E is greatly improved when consumption is accompanied with dietary lipids or fats. Absorption of vitamin E ranges from 20 to 50 percent, but may be as high as 80 percent, with absorption decreasing as intake increases (Bender, 1992). Dietary vitamin E absorption requires bile and pancreatic enzymes in the small intestine, where it is incorporated into micelles within the lumen of the small intestine. The micelles carry the vitamin E across the brush border of the small intestine and the vitamin E is then taken up by chylomicrons, which are transported by the lymph system to tissues and the liver. Vitamin E may be stored in the liver, adipose tissues, and skeletal muscle. When needed, vitamin E places itself in cell membranes. Excretion of vitamin E is by way of urine, feces, and bile (Wardlaw and Kessel).

Vitamin C (ascorbic acid) is a water-soluble antioxidant and is found in the water compartments of the body where it interacts with free radicals. It has been shown that short-term supplementation of vitamin C lasting two

to four weeks can significantly reduce the level of free radicals in the body (Naidoo and Lux). Dietary vitamin C is absorbed primarily by active transport in the small intestine, with absorption decreasing as intake increases. Approximately 70 to 90 percent of vitamin C is absorbed when dietary intake is between 30 and 180 mg/day. The kidneys excrete excess dietary vitamin C in urine, but excrete virtually no vitamin C when intake of the vitamin is very low (Wardlaw and Kessel). After absorption in the small intestine, vitamin C is transported in the blood to cells in its reduced form, ascorbic acid or ascorbate. The concentration of vitamin C varies in different tissues in the body. For instance, vitamin C concentrations are highest in the adrenal and pituitary glands, intermediate in the liver, spleen, heart, kidneys, lungs, pancreas, and white blood cells, and lowest in the muscles and red blood cells (Olson and Hodges). This vitamin may also possess some prooxidant properties, meaning it can participate in oxidizing other molecules such as iron in the blood stream (Alhadeff et al.).

Beta-carotene is a precursor to vitamin A (retinol). Beta-carotene is the most widely known compound in a group known as carotenoids, which are pigment materials in fruits and vegetables that range from yellow to orange to red in color. Carotenoids are also called proformed vitamin A because they can be made into vitamin A by the body when necessary. Carotenoids are pigments that are responsible for the orange color of many fruits and vegetables such as oranges and squash. Other carotenoids present in foods include antheraxanthin, lutein, zeaxanthin, and lycopene. Dietary retinol is usually found bound to fatty acid esters, which are in turn bound to proteins, and must undergo a process called hydrolysis that frees the retinol from the esters, enabling the retinol to then be absorbed in the small intestine. Proteolytic enzymes in the small intestine, such as pepsin, hydrolyze the retinol from the proteins. Approximately 70 to 90 percent of dietary retinol is absorbed provided there is adequate (10 grams or more) fat in the meal consumed (Olson). Carotenoids are absorbed at much lower levels, sometimes at levels as low as 3 percent, with absorption decreasing as intake increases (Brubacher and Weisler). Retinol and the carotenoids are carried through the absorptive cells of the small intestine by micelles for transport through the lymph system to the liver, which then can "repackage" the vitamins to send to other tissues, or act as the storage facility for the vitamins until needed by the body.

There are also enzymes that possess antioxidant properties. Glutathione peroxidase, superoxide dismutase, and catalase are the most well known. Glutathione peroxidase breaks down peroxidized fatty acids, converting them into less harmful substances. Peroxidized fatty acids tend to become free radicals, so the action of glutathione peroxidase serves to protect cells. The activity of glutathione peroxidase is dependent on the mineral selenium, which is the functional part of this enzyme, or

the part of the enzyme that makes it have antioxidant activity. Therefore, selenium is considered to have antioxidant properties. Superoxide dismutase and catalase react with free radicals directly, reducing their ability to oxidize molecules and cause cellular damage.

A class of compounds termed isoflavones, which are derived from soy, also have antioxidant activity. Genistein, daidzein, and prunectin are all able to prevent the production of free radicals. Isoflavone activity as an antioxidant plays an important role in the aging process and cancer prevention primarily due to having estrogen-related biologic activities in humans (Shils et al.).

The polyphenols (epicatechin, epicatechin-3-gallate, epigallocatechin, and epigallocatechin-3-gallate) found in jasmine green tea also possess natural antioxidant properties. Studies have shown that these polyphenols are able to protect red blood cells from destruction upon attack by free radicals (Shils et al.). The polyphenols present in red wine have also been found to be protective against the oxidation of low-density lipoproteins and high-density lipoproteins, which are very important factors in the prevention of the development of atherosclerosis or coronary artery disease (Ivanov et al.).

A final group of compounds, synthetic antioxidants, are often added to foods to prevent discoloration and delay oxidation of the foods after exposure to oxygen. They also help protect fats from rancidity. Rancidity causes fats to develop an unappealing flavor and odor. Most of the antioxidants used in foods are phenolic compounds. There are four antioxidants that are approved for use in foods, particularly fats. They are propyl gallate (PG), tertiary butylhydroquinone (TBHQ), butylated hydroxyanisole (BHA), and butylated hydroxytoluene (BHT) (Charley and Weaver). Sulfites, which are sulfur-based chemicals, are also used as antioxidants in foods. However, because some people may be very sensitive to sulfites and have adverse reactions to them in foods, the Food and Drug Administration has required that labels on foods containing sulfites alert the public to their presence.

### **Dietary Sources of Antioxidants**

Vitamin E is found in egg yolks, milk, plant and vegetable oils (including margarine and to a lesser extent butter), nuts, seeds, fortified whole-grain cereals, flatfish, halibut, shrimp, canned tuna in oil, asparagus, peas, tomatoes, apples, canned apricots in light syrup, blueberries, grapefruit, oranges, peaches, and pears. The milling process of whole grains causes most of the dietary vitamin E to be lost. The Recommended Dietary Allowance (RDA) as established by the U.S. Department of Agriculture currently is 15 International Units (IU) per day for men and 12 IU/day for women. In order for toxic effects to be produced, the amount of vitamin E consumed from foods would have to be 15 to 100 times the amount recommended for humans and this is extremely unlikely to occur (Wardlaw and Kessel). Symptoms and effects of

toxicity are discussed in detail in Signs and Symptoms of Antioxidant Deficiency and Toxicity, below.

Vitamin C is present in large amounts in broccoli, asparagus, cabbage, cauliflower, potatoes, tomatoes, apples, applesauce, apricots, bananas, blueberries, cherries, grapefruit, lemons, oranges, peaches, strawberries, kiwi, pineapples, pears, cranberries, and the juices and jams made from these fruits. The Recommended Dietary Allowance for vitamin C currently is 60 mg/day for both males and females. Vitamin C obtained from foods rarely can be consumed in amounts large enough to be toxic to humans (Wardlaw and Kessel).

Beta-carotene is found in liver (primary storage organ in animals for vitamin A), egg yolk, fortified milk, butter, spinach, carrots, squash, sweet potatoes, broccoli, tomatoes, peaches, mangoes, apricots, papaya, cantaloupes, and fortified breakfast cereals. Because beta-carotene is converted to vitamin A by the body, there is no set requirement. However, the RDA for vitamin A is set in Retinol Equivalents (RE) at the level of 625  $\mu$ g/day RE for men and 500  $\mu$ g/day RE for women (Wardlaw and Kessel).

### Diets High or Low in Antioxidants

Diets that are rich in antioxidants focus on high intakes of a variety of foods, especially large amounts of fruits, vegetables, and foods made from whole grains. Vegetarian diets, especially vegan diets (diets that exclude all foods from animal sources), are made up primarily from fruits, vegetables, whole grains, and legumes, and are an example of the types of diets that incorporate high levels of antioxidants. Another example of a diet that provides optimal levels of antioxidants is the Mediterranean diet. The Mediterranean diet is based on traditional eating habits in Greece, southern Italy, and Crete. This diet is rich in olive oil, foods from whole grains, and tomatoes, and minimizes the daily intake of poultry, eggs, sweets, and red meat. Red wine often accompanies meals in the Mediterranean diet and possesses some antioxidant activity (Murcia and Martinez-Tome). Furthermore, many of the spices used in Mediterranean cooking also have been observed to have some level of antioxidant properties (Martinez-Tome et al.). Asian-American diets also focus primarily on fruits, legumes, nuts, seeds, vegetables, and whole-grain food products, with liberal use of vegetable oils, while a minimum of meat is eaten. The traditional healthy Latin American diet provides beans, whole grains, nuts, fruits, and vegetables at every meal, with fish or shellfish, milk products, plant oils, and poultry being optional for daily intake.

Unfortunately, the typical American diet does not involve adequate intakes of fruits, vegetables, and whole-grain food products. This is not due to the lack of foods that fall into those categories but rather to the fact that too many Americans prefer fast foods and processed foods that are not rich sources of antioxidants. The Food Guide Pyramid developed by the United States Department of

Agriculture recommends that six to eleven servings of bread cereal, rice, and pasta be consumed daily; three to five servings of vegetables per day; two to four servings of fruit per day; two to three servings of milk products per day; two to three servings of meat, poultry, fish, dry beans, eggs, and nuts per day; and that the use of fats, oils, and sweets be sparse (Wardlaw and Kessel). Most Americans do not adhere to the guidelines of the Food Guide Pyramid and therefore do not receive adequate amounts of foods that provide large quantities of antioxidants.

Certain disease states make it difficult to obtain adequate amounts of fat-soluble vitamins due to an inability to digest foods with fat properly. The digestion and absorption of fat in foods is required for digesting and absorbing fat-soluble vitamins such as vitamins A and E. Individuals with cystic fibrosis, celiac disease, and Crohn's disease absorb fat very poorly, which also means that the fat-soluble vitamins are poorly absorbed. As the unabsorbed fat passes through the small and large intestine, it carries the fat-soluble vitamins along with it, and is eventually excreted in the feces (Wardlaw and Kessel). Chronic alcoholics are also at risk for not obtaining adequate amounts of antioxidants due to a marked decrease in food intake in favor of the consumption of alcohol. Alcoholism may also result in liver disease, which leads to an inability of the liver to store the fat-soluble antioxidants.

### Signs and Symptoms of Antioxidant Deficiency and Toxicity

Obtaining dietary intakes of vitamin E, vitamin C, and vitamin A from foods to meet the recommendations of the Food Guide Pyramid will prevent most healthy individuals from experiencing any deficiencies of these antioxidants. However, in diets that do not provide adequate amounts of fruits, vegetables, and whole grains, deficiencies may occur. It takes longer to develop a deficiency of the fat-soluble antioxidants, vitamins E and A, than it does to develop a deficiency of the water-soluble vitamin C.

Failure to obtain adequate vitamin E in the diet may cause certain medical conditions. Hemolytic anemia is caused by vitamin E deficiency, with an increased breakdown of red blood cells or hemolysis. Premature infants are most susceptible to vitamin E deficiency due to very small stores of the vitamin at birth and the frequently required use of oxygen to accommodate immature lungs. Premature infants are also growing very rapidly and need increased intakes of vitamin E. Special formulas are used to provide vitamin E to help prevent deficiency (Wardlaw and Kessel).

The disease caused by vitamin C deficiency is scurvy. The symptoms of scurvy are fatigue and small, purple spots or hemorrhages (petechiae) that appear around hair follicles on the back of the arms and legs. There are also bleeding gums and joints, impaired wound healing, pain in the bones, fractures, and diarrhea. Consuming a vitamin C-free diet for as little as 20 days may cause scurvy, but resuming vitamin C intake for one week can cause

the reversal of the disease and accompanying symptoms (Wardlaw and Kessel).

Vitamin E toxicity may result from intakes of more than 1,500 IU/day of vitamin E isolated from natural sources and 1,100 IU/day for synthetic vitamin E for adults nineteen years or older. It is only possible to acquire such high doses of either form of vitamin E via supplementation. Use of supplemental vitamin E at such high doses in persons with a compromised health status may lead to complications such as hemorrhaging in individuals who are taking anticoagulants or are vitamin K-deficient (vitamin K is important in blood coagulation) (Wardlaw and Kessel).

Vitamin C toxicity may occur at intakes of 2 g/day or higher. The symptoms of vitamin C toxicity are nausea, abdominal cramps, and osmotic diarrhea. Because vitamin C is a water-soluble vitamin, much of excess vitamin C obtained from supplemental megadoses is excreted in urine (Wardlaw and Kessel).

Small children who do not eat enough vegetables are at an increased risk for vitamin A deficiency. In fact, individuals with very low incomes and the elderly are also at risk for deficiency due to an inability to obtain adequate intakes of foods that are good sources of vitamin A and to the decreased gastrointestinal function that may occur with age. Night blindness is a symptom of vitamin A deficiency, causing the rod cells in the eye to take a longer period of time to recover from flashes of light. Another symptom of vitamin A deficiency is dry eyes caused by deterioration of the mucus-forming cells in the body. In an individual with dry eyes, dirt and other contaminants are not washed away, and this may lead to eye infections. If vitamin A deficiency is not corrected, the condition of the eyes worsens, leading to more serious disorders of the eye; eventually irreversible blindness may result. The skin is also affected by a compromised vitamin A status. Primary symptoms are very dry skin and rough and bumpy texture of the skin surface. When vitamin A supplements are taken long-term at three times the RDA a condition called hypervitaminosis A may develop. This condition can cause spontaneous abortions in pregnant women or birth defects in infants and therefore women of child-bearing age wishing to become pregnant should avoid using high doses of vitamin A supplements (Wardlaw and Kessel).

### **Maintaining Antioxidant Content in the Foods You Eat**

Antioxidants in foods are a valuable addition to a healthy diet and steps can be taken to preserve the antioxidant content of foods until they are ready to be ingested. Keeping fruits and vegetables refrigerated or in a cool, dry place helps to slow down the natural breakdown by enzymes that begins to occur as soon as the foods are picked. Fruits and vegetables should not be trimmed or cut until they are ready to be consumed to prevent unnecessary exposure to oxygen. Cooking by steaming, microwaving, or stir-frying in small amounts of fat for short amounts

of time also helps to preserve the vitamin content of foods. If liquids are used to cook fruits or vegetables, do not add fat while cooking if you are planning to discard the liquid before eating the fruits or vegetables, to avoid losing the fat-soluble vitamins that may be in the liquids. Finally, it is important to remember that the skin of some fruits and vegetables contains a higher vitamin content than the inner parts, such as the skin of an apple (Wardlaw and Kessel).

**APHRODISIACS.** Throughout the centuries, emperors and everyday folk alike have ingested, imbibed, sprinkled, or applied almost every conceivable substance—from almond paste to zebra tongues—in the hope of arousing sexual desire. Whether to woo a reluctant lover, revive a flagging libido, or pique carnal pleasure and performance, lovers the world over have relied on aphrodisiacs to do the trick. But which ones have the greatest reputations for potency (and why?) and do any of them really work?

### Aphrodisiacs through the Ages

The association between food and eroticism is primal, but some foods have more aphrodisiacal qualities than others. Biblical heroines, ancient Egyptians, and Homeric sorceresses all swore by the root and fruit of the mandrake plant. The grape figured prominently in the sensual rites of Greek Dionysian cults, and well-trained geishas have been known to peel plump grapes for their pampered customers. Fermented, of course, grape juice yields wine, renowned for loosening inhibitions and enhancing attraction (though as Shakespeare's porter wryly notes in *Macbeth*, alcohol "provokes the desire, but it takes away the performance"). Honey sweetens the nectarlike philters prescribed in the *Kama Sutra* to promote sexual vigor, and the modern "honeymoon" harks back to the old custom for newlyweds to drink honeyed mead in their first month of marriage. Grains like rice and wheat have long been associated with fertility if not with love, and *Avena sativa* (green oats), an ingredient in many over-the-counter sexual stimulants, may explain why young people are advised to "sow their wild oats." Numerous herbs and spices—basil, mint, cinnamon, cardamom, fenugreek, ginger, pepper, saffron, and vanilla, to name a few—appear in ancient and medieval recipes for love potions, as well as in lists of foodstuffs forbidden in convents because of their aphrodisiac properties.

Among other delicacies banned by the Church in centuries past were black beans, avocados, and chocolate, presumably all threats to chastity. And truffles—both earthy black and ethereal white—caused religious consternation in the days of the Arab empire. One story has it that the *muhtasib* of Seville tried to prohibit their sale anywhere near a mosque, for fear they would corrupt the morals of good Muslims. For those who held debauchery in higher esteem, the list of favored aphrodisiacs was bound only by the imagination. The herb valerian, noted for its stimulant properties at lower doses, was long a brothel favorite, and *yūjo*, professional women of pleasure in feudal Japan, supplemented their charms with the aphrodisiacal powers of eels, lotus root, and charred newts.

### From Symbol to Science

How did certain foods come to be regarded as aphrodisiacs in the first place? In some cases, legendary associations play a likely role: Cleopatra is rumored to have rubbed her private parts with a honey-almond mixture that drove Mark Antony mad. Some believe that the Aztec

Aphrodisiacs flirt with the libido, and in this advertisement for vodka, the message is clear, yet subtle. Sparkling crystal, silver glasses, and caviar imply indulgent luxury, yet it is the glasses for two and the beautiful woman in the background that tells us that this intimate indulgence will also lead to love. PHOTO COURTESY OF STOLICHNAYA RUSSIAN VODKA.

ruler Montezuma fortified himself with upwards of fifty cups of chocolate before visiting his harem (though more scholarly reports contend it was the conquistadors who sought such reinforcement). Casanova famously boasted of seducing a virgin by slipping a raw oyster into her mouth. Madame du Barry is said to have used ginger in a custardy concoction that stirred Louis XV to passion. And because Aphrodite, Greek goddess of sexual love, was said in myth to be born from the sea, a beguiling array of seafoods have been deemed aphrodisiacs (her very name is the source of the word).

Symbolism, too, plays an obvious part. During the Middle Ages, the Law of Similarities, or Doctrine of Signatures, held that in God's universe "like causes like," so suggestively shaped and textured substances were believed to enhance virility and fertility by virtue of their resemblance to sexual organs. Firm, elongated asparagus, sea cucumbers, and ginseng (literally, "manroot") and moist, fleshy figs, peaches, and oysters are prime examples. Other symbolic aphrodisiacs are rhinoceros horn and deer antler and the sex organs of animals known for their virility or procreative fervor, such as the tiger or rabbit.

Some foods are exalted as aphrodisiacs by virtue of their rarity or luxury. Bird's nest soup, *foie gras*, caviar,

## THE NOTORIOUS SPANISH FLY

Cantharides, a potent preparation made from the crushed dried bodies of the green blister beetle, has been famed throughout history as an aphrodisiac. The Marquis de Sade reportedly favored Spanish fly to enhance virility, and an entire legion of nineteenth-century French soldiers “stood at attention” for prolonged periods after feasting on frogs that had themselves been dining on cantharidin-laden beetles.

Spanish fly does indeed produce erections, but one might die for the pleasure: the French legionnaires in question suffered from priapism, persistent painful erections that, untreated, can result in scarring and permanent loss of erectile function. Antonio Gamoneda in *The Book of Poisons* noted that “Great injury befalls those who take the Spanish Fly, because they will feel a burning corrosion in almost all their body. . . . They will suffer from swoons, surfeit, and lightheadedness, and will fall to the floor and gnaw table legs.” This urogenital-tract irritant can be deadly and should be avoided.

Fortunately, safer drugs are now available to aid impotence, and people experiencing sexual dysfunction are well advised to seek medical advice.

truffles, and champagne are all, even if no longer necessarily difficult to obtain, still suggestive of wealth and largesse, playing into the age-old association among food, sex, and the provision of resources. Certain foods also lend themselves to particularly sensual dining rituals and modes of eating. Preparing food tableside with competence and élan, consuming whole ripe fruits or succulent birds or crustaceans, eating with the hands, licking fingers coated in delectable juices, feeding one’s partner, sharing food from a common platter, sucking and slurping seductively—such acts and rituals constitute true foreplay for culinarily inclined lovers.

“No one has ever succeeded at seduction by means of food alone,” wrote Manuel Vázquez Montalbán in his *Immoral Recipes*, “but there’s a long list of those who have seduced by talking about that which was about to be eaten.” Certainly, stimulating the mind helps stoke the sexual appetite, and it is our social and cultural associations that imbue certain foods with erotic meanings. But is there solid scientific evidence to support the claims made for aphrodisiacs beyond their placebo effect?

Proponents of chocolate point out that it contains phenylethylamine, or PEA, the brain chemical believed to underlie the euphoric sensation of being “in love.” But eating chocolate has not been found to actually increase

PEA levels in the body. The chili pepper may have a stronger claim to its fiery reputation: it quickens the pulse and induces sweating, mimicking the state of sexual arousal, and has also been shown to stimulate the release of endorphins, naturally occurring opiates that play a role in sexual pleasure. Ginkgo biloba, said to boost both mental and sexual performance, may restore or enhance physical function by increasing blood flow to the genitals, but the safety and efficacy of this herbal enhancer are still unclear (heart patients and those on aspirin need to be especially cautious). Garlic may promote potency through a similar mechanism, with its high content of arginine, an amino acid that enhances blood flow and could thereby augment erections. The lure of the elusive truffle may derive in part from a pheromonelike chemical it contains, similar to one secreted in the saliva of male pigs to attract sows. And the oyster, that consummate aphrodisiac, is noted not only for its fleshy, briny sensuality but also for its rich supply of zinc, which may aid normal sperm production and libido (though it is unlikely that oysters make a difference in any but the most zinc-deficient diets).

## The Ultimate Aphrodisiac

Overall, aphrodisiacs seem to be more the stuff of folklore than of science. But in the realm of food and love, the power of the imagination is not to be ignored—believing something’s an aphrodisiac may well make it so. Yet all the oysters in the world cannot take the place of the ultimate aphrodisiac. As the Roman philosopher Seneca once promised, “I will show you a philter without potions, without herbs, without any witch’s incantation—if you wish to be loved, love.”

**APICIUS.** The proverbial gastronome Apicius (M. Gavius Apicius, c. 25 B.C.E.–c. 37 C.E.), who lived at the

## ANCIENT CASSOULET

Conchic[u]la à la Apicius (one of several ancestors of a cassoulet)

Conchiclam Apicianam: accipies Cumanam mundam, ubi coques pisam. Cui mittis Lucanicas conchisas, esiciola porcina, pulpas petasonis. Teres piper, ligusticum, origanum, anethum, cepam siccam, coriandrum viridem, suffundis liquamen [garum], vino et liquamine temperabis. Mittis in Cumanam, cui adicies oleum, pungis ubique, ut combibat oleum. Igni lento coques ita ut ferveat et inferes. (V, iv, 2)

Take a clean Cumaean pot [earthenware from Cumae] in which you cook the [dried] peas. Into this add Lucanian sausages, cut up; little pork meatballs; and pieces of pork shoulder. Pound [in a mortar] pepper, lovage, oregano, dill, dried onion, green coriander and moisten with *liquamen* [oriental fish sauce, for saltiness]; blend with wine and *liquamen*. Put this in the Cumaean pot, to which you add [olive] oil and prick [the seasoned meats and peas] all over so that the oil is absorbed. Cook over a low fire that it may simmer, and serve.

ED. NOTE: The dried whole peas, or beans, should be soaked overnight before cooking; in other dishes of this chapter the peas are first cooked with leeks, coriander [cilantro], and mallow flowers. Elsewhere Apicius gives a recipe for preparing Lucanian sausage in which the minced meat is seasoned with pepper, cumin, savory, rue, parsley, bay leaves, and *garum* [oriental fish sauce such as *nuoc mam* etc.], plus “condiments”; the latter justifying the use of preserved duck, comparable to certain French cassoulets; finally whole peppercorns, pine nuts, and bits of fat are added before the meat is packed into intestines and hung to smoke. It is possible to use Italian sausage like that from Abruzzi, or even Chinese sausages. Bake in a slow oven.

time of the emperor Tiberius, gives his name to the most complete cookbook that has come down from antiquity, one that reflects an ancient Roman cuisine that survives, in part, in early-twenty-first-century Italian traditional practice and that has also shaped European cookery, whenever cooks—or their employers—wished to touch base with ancestral foodways. The book, *De re coquinaria* (On Cookery), is actually the product of a Late Antique compiler, writing about 400 C.E., who drew from an agricultural treatise, a work on household economy, and a Greek study of dietetics, in addition to two genuine publications by Apicius: a general cookbook plus a more specialized one on sauces. Over the years, scholars have been able to establish the true name of Apicius; in the past he was known as Apatius Caelius. Because of abbreviations in the headings of one of the ninth-century manuscripts that preserved the text, his identity was further confused by “ghosts” created through scribal errors of transmission (Three gourmets of that name did not exist, as some authors still have it).

Copying over 450 recipes, our anonymous “editor” organized his gleanings into ten books or chapters, giving each a pretentious Greek name: *Epimeles*, the prudent housekeeper (conserves and preservation advice); *Sarcopetes* (minced meats such as sausages, quenelles, and the like); *Cepuros*, the gardener (vegetables); *Pandecter* (compound dishes of many ingredients); *Ospreon* (legumes, such as peas, beans, chick-peas, and lentils); *Aeropetes* or *Trophetes* (fowl, both wild and domestic); *Politeles*, gourmet dishes (including eggs and limited sweets for *bel-laria* or the dessert course); *Tetrapus* (quadrupeds both wild and domestic); *Thalassa*, the sea (shellfish, crustaceans, cephalopods); and *Halieus*, the fisherman. An independent selection of thirty-one Apician recipes, recorded in an early medieval manuscript, represents *excerpta* made by one Vinidarius, apparently an Ostrogoth of the period of King Theodoric at the end of the fifth or early sixth century, and includes an impressive list of the herbs, roots, and seeds (spices) that should be at hand in a prosperous kitchen.

From Carolingian manuscripts of *De re coquinaria*—two of which survive in the New York Academy of Medicine and in the Biblioteca Apostolica of the Vatican—Italian Renaissance humanists commissioned numerous copies. The first printed edition of 1498 was shared in two issues between the printers G. Le Signerre in Milan and Ioannes de Legnano, the latter reprinted anonymously in Venice at the end of the century, and again by Tacuinus in 1503. Physicians stand out among subsequent editors: G. Humelberg of Zurich (1542) and Martin Lister (1705).

Seneca tells of Apicius committing suicide when he discovered that his assets—still representing considerable wealth—seemed not enough to enable him to continue dining with his accustomed extravagance, while the elder Pliny castigates his gluttony by reference to his partiality for flamingo tongues. Anecdotes accrued to his repu-

tation long after his death, such as the tale of his storm-tossed voyage to the coast of Libya in search of the largest, most succulent prawns; when the shrimp did not meet expectations he ordered the hired ship to turn back to home port without his setting foot on land to recover from the journey. One indulgence of Apicius is enshrined in the Italian language. His invention of feeding swine on figs, thus engorging their livers, and then giving them honeyed wine (the Roman apertif *mulsum*) so that the pigs might die in ecstasy, their livers deliciously *ficcatum* (literally, “figged”), gave rise to the word for all liver, *fegato*.

Apicius's recipes, without proportions or details of procedure, reveal the extent to which Roman cookery, although lacking such New World products as quintessentially Italian as tomatoes and capsicum peppers, or medieval Arabic imports like spinach and eggplant, nevertheless survives in Italian *agrodolce* tastes, a love of pasta and farro, an ingenuity in sausage making, and the use of drastically reduced wine or must in sauces (from ancient *passum* to *sapa*, for example). It also provides both name and concept to Mediterranean dishes such as paella, tian, and cassoulet.

**APPETITE.** Appetite is a term implying a strong desire to acquire or participate in, exemplified by terms such as sexual appetite or appetite for life. In the context of food, appetite is used to describe a wanting or liking for particular foods, usually on the basis of their sensory properties (taste and texture) or a psychological attribute (perceived value or symbolic status). In this way appetite is usually distinguished from hunger, which implies a desire or seeking for food arising from a state of need or nutritional deficit. At the beginning of the twenty-first century the understanding of appetite achieves special importance because of its potential role in the worldwide epidemic of obesity, sometimes called a pandemic. Given that, in many parts of the world, people are surrounded

by a plentiful supply of food that prevents chronic hunger (though permitting normal meal-to-meal hunger), the capacity to eat food in the absence of hunger or in a low state of hunger assumes special importance. Consequently, understanding appetite and how it can be controlled are urgent tasks in the fight against the obesity epidemic.

Appetite can therefore be defined as a liking for particular foods, or an attraction for foods based on their perceived pleasantness. This is normally referred to as the hedonic dimension of food selection. This characteristic can be described as the subjective pleasure that is derived from the consumption of food; in turn, this can be measured by asking people to rate the magnitude or intensity of pleasure associated with eating or tasting foods. This pleasure arises from the interaction between the person's perceptual capacity (acuity of taste, smell, and sensory feedback from the mouth) and the physical properties of foods. The intensity of the pleasure therefore depends in part on internal (personal) and external (food-related) factors. These food factors can be natural, such as the presence of sweet carbohydrates in fruits or, and much more common now, the deliberate construction of powerful properties in the manufacturing process. It can be hypothesized that the industrial production of foods (designed to possess a combination of properties, for example, sweetness, fattiness, flakiness) has saturated the food supply in many parts of the world with an abundance of appetite-stimulating products. These products include chocolates and desserts, cheese, meat, and pastry combinations, and many types of fried snacks. The inherent attractiveness of such products can stimulate eating in the absence of any obvious need for nutrients.

#### Biological Basis of Appetite

Is there a biological basis for appetite and for the degree of attractiveness of specific types of foods? It does seem that human beings derive pleasure from particular food properties—the qualities of sweetness and fattiness are prominent. It is generally understood that, during the course of human evolution, a preference for foods with these properties would lead people to consume foods that possessed energy—yielding value, for example, the nutritional value of carbohydrates and the energy value of fats. Consequently the value of these traits for survival has almost certainly persisted until the present day, at which stage these genetic dispositions may be detrimental in the current "obesogenic" environment (but useful when foods with these properties were scarce). The word "obesogenic" was coined around the end of the twentieth century to suggest an environment that promoted weight gain through the abundance, attractiveness, and marketing of food consumption, together with reduced opportunities for physical activity. It is recognized that most cultures contain highly prized food habits based on foods that are either sweet or fatty, and sometimes a combination of both—when the palatability can be intense.

Do these genetic traits based on the pleasurable qualities of food have a basis in brain processes? The intrinsic sensory attractiveness of food is mediated by “reward” pathways in the brain. These pathways promote various types of pleasure and can be artificially stimulated by drugs. By using drugs as tools it has been found that particular neurochemical transmitters are involved in the process of reward; these transmitters include dopamine, opioid, and cannabinoid molecules together with their specific receptors. It can also be demonstrated empirically that the areas of the brain that subserve the most intense pleasure can be stimulated both by food sensations (arising from sensory pathways), and modulated by signals of need (arising from the body’s energy stores). This means that a nutritional deficit, indicated by a low body weight, for example, can sensitize the reward system so as to increase the measured pleasantness of foods. In practice this would mean that a person who had been coerced into losing substantial body weight would display an increased rating of pleasantness for certain foods. This can be seen as a useful biological mechanism and is given credibility via the long-known phenomenon called *alliesthesia*, which is perceiving an external stimulus as pleasant or not, depending on internal stimuli. This concept is based on the biological notion of pleasure being a useful trait.

However, it seems certain that another mechanism must also be at work. This mechanism is based on the recognition that some people who gain weight easily and become obese possess traits that lead them to derive a high degree of pleasure from food. Consequently, foods with potent sensory properties are attractive targets for such people and this increasing pleasantness can lead to overconsumption and weight gain. There is clear evidence that obese women rate sweet/fatty foods very highly and consume substantial quantities; other studies have shown that obese people show preferences for fatty foods and for the taste of fat. After eating, obese subjects frequently rate the same food as being more pleasant than do lean subjects. In this way the expression of appetite—a heightened pleasure of eating—can be seen to contribute to increasing body weight and obesity. This arises from endogenous traits to derive pleasure from food (sometimes specific foods) in conjunction with an abundance of foods possessing a profile of pleasure-stimulating properties.

### Hedonics and Hunger

The identification of the pleasure response of appetite with a neurochemical substrate also helps to differentiate the hedonic dimension of food from the hunger dimension. The term “hedonic,” derived from the Greek word *hedone*, refers to the seeking of pleasure. Experimental studies in human subjects have shown that a drug called naloxone that blocks opioid receptors can reduce the perceived pleasantness of food without diminishing hunger. In contrast a drug such as fenfluramine, that acts

upon serotonin receptors, can substantially reduce hunger without changing the perceived pleasantness of food. This type of pharmacological dissection indicates that the overall control of food intake depends upon both appetite (signals of pleasure) and hunger (signals of absence of food). However, the separation of the systems is not complete since experimental investigations have shown that while people are eating very good-tasting food their hunger is elevated. This elevation serves to prolong the meal so that more food is consumed. The relationship is, however, asymmetrical: although pleasantness increases hunger, a state of satiety does not reduce the perception of pleasure. Indeed, even when people report feeling full, a very palatable food can often still be eaten. Surveys have shown that foods rated as most palatable (pleasant) are associated with the largest meal sizes and with the greatest amount of food consumed. The results of scientific observations are therefore consistent with the widespread belief that people eat more of good-tasting food. However, people do not always choose to eat the most delectable or most pleasure-giving food; eating also depends on the appropriateness of the food for the particular social context. This is a good example of a cultural rule overcoming a biological response. However, much overeating in certain cultures arises from the strength of the biological response or perceived intensity of pleasure overcoming the cultural convention.

### The Palatability Dilemma

The potency of appetite in stimulating food consumption creates a problem in the present climate of escalating levels of obesity. There are now strong intentions in the nutraceutical sector of the food industry to encourage the production of functional foods for appetite control; that is, foods that possess satiety-inducing or hunger-suppressing properties. The word “nutraceutical” was coined to resemble the word “pharmaceutical” and refers to those foods that may have specific functional effects generated in a manner similar to the way in which drugs work. However, advances in food technology have, over the years, been able to bring about an increase in the overall pleasantness (palatability) of foods entering the market-place. Indeed, one of the legitimate goals of the food industry is to make eating a source of pleasure. It can be observed that for many people, eating is the cheapest form of pleasure available on a day-to-day basis. However, improving palatability means increasing the sensory attractiveness of foods and the willingness of people to consume such foods. Satiety implies reducing the willingness of people to consume. The question therefore arises whether it is possible for the food industry to increase the palatability of foods without weakening satiety—and vice versa. The balance between palatability and satiety is the essence of the interaction between hunger and hedonics in the control of food intake. It remains to be determined how the interplay between these factors contributes to the current obesity epidemic.

**APPLE.** Picking apples on a clear, crisp, sunny autumn day provides a cornucopia of pleasures. The enjoyment of being outdoors and savoring another harvest has been part of the human experience for centuries. Biting into a crunchy, sweetly flavored apple or quaffing a big glass of fresh cider reminds one why apples are a part of fairy tales and folk history. Remember Snow White and Johnny Appleseed? Apples have sustained humans with beverages—hard and sweet cider—innumerable culinary dishes, winter provisions, and even foodstuffs for hogs and cattle, and they are still an integral part of American culture and commerce. Apple pie is the quintessential American dessert, and bins of fresh apples are present year-round in every supermarket. An apple variety exists for every taste bud, and eating apples has a lot of health benefits, too. They are a good source of antioxidants and fiber, and an individual apple contains about 80 calories, 5 grams of fiber, 6 milligrams of vitamin C, and 170 milligrams of potassium.

#### Origin of Apples

Botanists theorize that apples originated somewhere in central and southern China. This area is home to around twenty *Malus* species, whose seeds were gradually spread by birds throughout the Northern Hemisphere. Ornamental crab apples are also descendants of these smaller, bitter-fruited species. It was thought that the edible apple (*Malus domestica*) evolved as a complex hybrid from a number of these wild apple species. However, Barrie Juniper, emeritus fellow in the Department of Plant Sciences at Oxford University, has suggested that a small population of a single *Malus* species from the wild forests

of the Tian Shan (the Heavenly Mountains) along the border of western China and Kazakhstan is the progenitor of all modern apple cultivars. These Tian Shan forests became isolated by biological and climatic changes about 4.5 million years ago and evolved in isolation. Juniper theorizes that as bears and wild pigs, horses, and donkeys gradually began to occupy the area and to eat the largest and sweetest fruits, they aided in the process of natural selection for larger, sweeter fruit. Because apples do not breed "true to type" from seed, these wild plantings from dispersed seeds gradually contributed to a diversity of apple varieties from this one species. Later, around ten thousand years ago, humans began to travel through the area and also began to eat these fruits and to carry them westward. Juniper and other researchers are studying the remnants of these forests of wild fruit trees and are collecting samples for DNA analysis. These wild fruit trees are a fruit breeder's paradise for genetic material.

#### Ancient History

By 2500 B.C.E. apples were cultivated throughout northern Mesopotamia and Persia. The walled gardens of Persia included fruit trees for their ornamental beauty as well as for their culinary delights. The ancient Greeks and Romans also cultivated apple orchards, and their wealthy citizens enjoyed apples as part of the dessert course at banquets. The Greeks, well advanced in horticultural knowledge, understood grafting and propagated specific varieties for their orchards. The Greek writer Theophrastus knew that apples would not grow true to type from seeds, writing, "Seedlings of . . . apples produce an inferior kind which is acid instead of sweet . . . and this is why men graft." In the first century C.E. the Roman writer Pliny described over twenty named varieties in his *Natural History*. Apple orchards were established throughout continental Europe and in Britain as the Romans extended their empire, culture, and crops. An indicator of the importance of the apple in these ancient cultures is its prevalence in Greek and Roman mythology. The Roman goddess Pomona tended her orchards and bestowed gifts of fruit on her favorites as rewards for favorable acts.

After the collapse of the Roman Empire, many of the favorite dessert apple varieties of the day disappeared. Charlemagne's rise to power in 771 brought a measure of peace and prosperity and an increased interest in horticultural pursuits. His *Capitulare de Villis* (Rules of Land Use) decreed that every city should include apples, cherries, plums, peaches, and pears. Charlemagne also issued an edict that brewers (which included cider makers) should be encouraged to develop their trade. Apple cultivation and varietal development progressed in Europe during the Renaissance. Varieties were selected, named, and propagated, and orchard plantings increased. These improved varieties were included in beautiful displays of fresh fruit at Renaissance banquets, where fresh apples were enjoyed as part of the dessert course.

## North American History

Apples have been part of American life from the first arrival of European settlers. One of the first documented orchards in the New World belonged to William Blaxstone, a well-known horticulturalist and clergyman. He planted his orchard around 1625 on the slope of what became Beacon Hill in Boston. Blaxstone, who was described as an eccentric, saddle-trained a bull and distributed apples to his friends on his rides. One of his apples, Sweet Rhode Island Greening, is probably the first named variety from the United States.

**Colonial America.** A one- to six-acre apple orchard was an important part of farmsteads in seventeenth- and eighteenth-century America. Apples were grown primarily for hard cider, which was the beverage of choice because water was regarded as unsafe. Everyone in the family drank cider, and each family produced twenty to fifty barrels of cider each autumn for its own consumption and to use as barter for needed goods and services. Cider was not considered prime until it had aged over a year. Applejack, made from distilled cider, was even stronger. The first cider mills were built around 1745. Prior to this cider was made by pounding apples in a trough and draining the pomace. By the late eighteenth century cider mills dotted the countryside. In New England one in ten farms had a cider mill.

Cider was also used in cooking apple butter. Sweet cider (the unfermented, freshly pressed juice) was combined with peeled and boiled apples and cooked until the mixture had been reduced to a thick paste through evaporation. It was then put up in earthen jars for later use. Some cider was allowed to become vinegar and was used for food preservation. Apples were also dried for winter preservation. Michel Crèvecoeur, author of *Letters from an American Farmer* (1782), described drying apple slices on wooden platforms erected on poles. The fruit was spread out on wooden boards, where it was soon covered with “all the bees and wasps and sucking insects of the neighborhood,” which he felt accelerated the drying process. The dried apples were used for apple pies and dumplings throughout the year. Peaches and plums were also dried but were considered more of a delicacy and were saved for special occasions. The dried apples, also called schnitz, were stored in bags hung in the attic rafters to keep them dry and away from mice. The Pennsylvania Dutch, German settlers in eastern Pennsylvania, were prodigious apple growers and developed a brisk business in colonial America selling schnitz, apple butter, and cider. A traditional Pennsylvania Dutch apple dish, called schnitz pie, consists of dried apples first cooked in water; then sugar and spices are added to the pot, and finally the mixture is baked in a lidded pie crust. *Schnitz and knepp* is a dish of ham, potatoes, and dried apples cooked together; dumpling dough is added and cooked briefly right before serving.

After the Revolution, grafting and nurseries became more commonplace. Still, until the mid-nineteenth cen-

Cleft grafting on fruit trees according to a medieval method described by Pietro Crescenzi (ca. 1233–ca. 1320). From a woodcut in the *De Omnibus agriculturae partibus*. ROUGHWOOD COLLECTION.

tury most plantings in home orchards were of seedling trees that were not pruned. The fruit was primarily used for cider and fed to hogs. Pork was cheap, and the abundant apples and peaches were an inexpensive way to fatten pigs. Cider was even part of political campaigning and was dispensed freely during voting time. During one election, George Washington’s agent is said to have dispensed 3.75 gallons of beer, wine, cider, or rum to every voter.

Insect pests and diseases were not quite as prevalent in colonial times as they later became. Some key fruit pests had not yet made the trip to the New World, and other native insects had not yet discovered apples. Pest-damaged fruit was also accepted as natural and unavoidable. Still-life paintings of fruit from this and earlier eras clearly show insect and disease damage on the fruit. In 1806 Bernard McMahon, in *The American Gardener’s Calendar*, instructed readers to pick the worst of the leaves off the tree and dash the branches with water in dry weather to prevent insect damage from spreading.

Johnny Appleseed, whose real name was John Chapman, was a popular folk character in early nineteenth-century America. Born in Leominster, Massachusetts, in 1774, Johnny Appleseed started seedling apple tree nurseries throughout Pennsylvania, Ohio, and Indiana. Traveling by canoe or on foot, he gave apple seeds from cider mills to any farmer who promised to plant them and take care of them. On his travels he also planted seedling nurseries in clearings. At his death in 1847, he had established apple trees over 100,000 square miles of territory.

**Nineteenth-century apple growing.** Agricultural settlement of midwestern and western states by European settlers began in the mid-1820s. Home orchards were planted in Washington State by the first European immigrants from the eastern states in the mid-1800s. Commercial orchard plantings did not take hold until the

Harvested apples at Brogden Farm in Kent, England, are being boxed for distribution to the London market. Kent lies at the center of Britain's apple-growing region. © HULTON-DEUTSCH COLLECTION/CORBIS.

advent of the big irrigation projects in the late nineteenth century. By 1850 five hundred named varieties were cultivated. The seedling nurseries started by Johnny Appleseed and settlers across the country were the start of unique American varieties like Baldwin, Esopus, Spitzenburg, Green Newton, Jonathan, Hawley, Newton Spitzenburg, Swaar, Winesap, and York Imperial.

The mid-nineteenth century saw changes in American agriculture as urban populations grew and a smaller percentage of people were involved in agriculture. Apple growing was no longer primarily the purview of the self-sufficient homestead. Alcoholic cider fell into disrepute with the spread of the temperance movement, and the cider industry declined. Larger commercial orchards were established for growing and selling fresh apples. The apple industry was affected between 1880 and 1930 by the development of the refrigerated railroad car that allowed fruit growers in the western states to ship fruit east. The development between 1910 and 1920 of refrigerated storage meant that long-keeping winter apples were not as necessary, so fewer varieties were grown by commercial orchards. At the beginning of the twentieth century seven thousand named varieties of apples existed, but five thousand of these varieties were extinct by the beginning of the twenty-first century. Prior to refrigerated storage, apple cultivars grown in small orchards varied from early-season baking apples to winter-keeper types with a thick, waxy skin that would store well in root cellars.

### Pest Management

Pesticides were not developed or widely used until the late nineteenth century, when growers began producing fruit more for market and for fresh eating rather than for cider and for home consumption. Orchardists experienced increasing pest damage from codling moth, a lar-

val fruit pest accidentally introduced from Europe by early settlers, and from other pests and diseases. The first arsenical insecticide, Paris green (copper acetoarsenite), was developed in the 1870s to control codling moth. Lead arsenate was developed as an insecticide in 1892. Growers also began using nicotine sulfate to fortify the lead arsenate applications. At first these broad spectrum, toxic pesticides were applied one to three times during a growing season, but the number of applications increased as codling moth became more difficult to control. By 1945 orchardists were using up to seven applications of lead arsenate each season. DDT, developed during World War II, was hailed for its effectiveness against insect pests and low toxicity to humans. Not until later did scientists discover that DDT persisted in the food chain. Still, these new pest controls were not without concerns. DDT successfully controlled codling moth but wiped out natural predators that kept other pests in check, so the number of pests that needed to be controlled greatly increased as the number of pesticides increased.

Public debate over pesticide use grew with the increasing use of pesticides. In 1937 the U.S. Congress directed the U.S. Public Health Service to investigate the possible harmful effects of spray residues on fruits and vegetables. Although the Service's report, finished in 1940, concluded that harmful effects were minimal, the dialog about pesticide use continued, reflected in various scientific studies and public debates through the decades. The 1962 publication of *Silent Spring* by Rachel Carson galvanized public opinion about the environmental consequences of pesticide use.

### Apple Orchards in the Twenty-First Century

The introduction of integrated pest management in the 1970s placed more emphasis on understanding pest and disease life cycles and pest populations as the basis for pesticide applications instead of touting the benefits of applying sprays on a routine basis. Still, fruit growers must meet the demand for inexpensive, blemish-free fruit in a competitive marketplace. Pesticide use on apples remains higher than on most other crops. Researchers continue to study pest- and disease-monitoring techniques, biological controls, and new targeted pesticides to develop more ecologically based production systems and to lower the pesticide risk for agricultural workers and consumers. Consumer demand for organic fruits and vegetables produced without synthetic pesticides and fertilizers has increased. Organic apple production is growing, particularly in the Northwest, which has fewer insects and diseases than the Northeast.

In the early twenty-first century Washington State produced 50 percent of the apple crop in the United States, followed by New York, California, Michigan, and Pennsylvania. Although over two thousand varieties of apples are grown in the United States, commercial orchards produce about 90 percent of the crop from ten varieties of apples—Red Delicious, Golden Delicious,

Granny Smith, Rome, Fuji, McIntosh, Gala, Jonathan, Idared, and Empire. Controlled atmosphere storage, where the oxygen level is decreased and additional nitrogen is introduced into refrigerated storage, means apples can be stored from one season to the next and hold their quality. Approximately 50 percent of the crop is sold for fresh eating; 20 percent is processed for vinegar, cider, juice, jelly, and apple butter; 17 percent is canned as applesauce and pie filling; and 13 percent is exported. Internationally apples are the most widely cultivated tree fruit. Annual world apple production stands at approximately fifty-seven metric tons of apples. China is now the world's largest producer of apples, followed by the United States, Turkey, Italy, Germany, France, Iran, Poland, Argentina, and India.

### Horticultural Requirements

Commercial apple orchards require skilled management. Apples are adaptable but grow best in cool temperate climates from about 35 to 50 degrees latitude. Most apple varieties require full sun, good soil drainage, and a chilling period (1,000 to 1,600 hours of temperatures below 45°F) and 120 to 180 frost-free days to produce a crop. Fruit quality is highest when day temperatures are warm but nights are cool. Orchardists favor trees that have been propagated on size-controlling rootstocks. These rootstocks produce smaller trees that can be planted more intensively, yield more per acre, and bear fruit earlier (two to four years) than full-sized standard rootstocks. Trees are pruned annually, and pests, diseases, soil fertility, and water needs are monitored to maximize fruit quality, size, and color. Growers must also pay attention to market demands and price fluctuations to maintain viable businesses in a highly competitive international arena.

One option for smaller family farm operations is to focus on direct marketing to the consumer. Roadside marketing, farm markets, and pick-your-own operations can emphasize locally grown, unique apple varieties. Large-scale supermarkets tend to carry only a few varieties, while the several thousand apple varieties once grown in the United States are unknown to many consumers. Apple aficionados can search out regional favorites like Smokehouse, a fine, old Delaware and Pennsylvania apple from 1837; Grime Golden, the rich, distinctive apple from the mountains of West Virginia; or Blue Permain, a large, dark purplish-red fruit that will keep all winter in a root cellar. The best baking apples are found at farmer's markets. The tart Lodi ripens early in the season, Fallawater is an old favorite for both baking and eating, and the yellow-fleshed Smokehouse is juicy and firm for pies.

Preserving the rich heritage and genetic diversity of these varieties is a concern of the Seed Savers Exchange, a nonprofit organization devoted to saving heirloom varieties of vegetables and fruits. The organization maintains a historic orchard of seven hundred apple varieties at its Heritage Farm in Decorah, Iowa, and aims to obtain cuttings of all existing nineteenth-century apples.

The U.S. Department of Agriculture also maintains an apple germ plasm collection of more than three thousand varieties in orchard plantings or in tissue culture storage. These collections offer genetic characteristics, such as insect and disease resistance, flavor, fruit size, and cold hardiness, that are important in breeding new apple cultivars.

### Home Gardening

The general perception among gardeners is that apple growing is too complicated and is best left to experts. Backyard apple-growing enthusiasts know that, while apple growing does take an investment of time and knowledge, it really is not difficult. Some homework will determine the varieties and size-controlling rootstocks that thrive in an area. Local agricultural extension agents are good resources for information on which pests and diseases might present problems. The North American Fruit Explorers (NAFEX) is a network of fruit-growing enthusiasts who publish a quarterly journal of helpful varietal and growing information. Disease-resistant varieties, such as Liberty, Redfree, Gold Rush, and William's Pride, are an absolute boon for backyard orchardists. Gardeners can combine the disease-resistant varieties with insect-trapping techniques, like the apple maggot trap, which is a red apple-sized sphere coated with sticky tanglefoot to attract apple maggots, and kaolin clay, a fine clay particle spray material, to produce a good-quality apple without inundating a backyard with pesticide materials. Harvesting a basket of crisp, delicious apples from a backyard orchard should be on every gardener's wish list.

**AQUACULTURE.** Aquaculture, the controlled or semi-controlled production of aquatic plants and animals, has increased at double-digit percentage rates since the early 1980s. This increase has been in response to declines in commercial harvests of wild stocks of fish and shellfish. Oceans of the world are currently at maximum sustainable yield. Since the late 1980s, there has been a concerted effort to maintain global commercial harvest of ocean fish at approximately 100 million metric tons (mmt). However, as global population grows, demand for fish and shellfish increases, and the percentage of aquatic products grown in aquaculture must likewise rise to meet the supply of those products. Projections for increased production are in the range of 40–100 mmt of new aquaculture production by about the year 2030. The lower range assumes only increases in world population; the upper figure represents increases in world population plus a 1 percent per year increase in per capita consumption. To put this number in perspective, the 1995 world production figures for soybeans was 137 mmt, swine was 83 mmt, and chickens was 46 mmt. Thus, to meet demand in the first part of the twenty-first century, we must realize significant growth. This increase in production will not be accomplished with a single species.

There are fewer than thirty large species-specific aquaculture industries globally, and the fourteen largest industries are listed in the table. However, there are over twenty-five thousand species of fish and there are estimates that one thousand new species are being evaluated for their culture potential. The small percentage of species raised relative to the total number available is an indication that aquaculture is a new concept in many parts of the world. As a subsistence enterprise, aquaculture has been practiced for over four thousand years. As a series of large industries, aquaculture is less than fifty years old, often stimulated by declining wild stocks of fish. The channel catfish industry, which only began in the late 1960s in the southern United States, is illustrative of a relatively young industry. Today, over 90 percent of the U.S. supply of Atlantic salmon is cultured. In 1980, that figure was a fraction of 1 percent, at most. The global supply and demand characteristics created a good deal of volatility in production, which has only increased over time. Additional factors such as identification of new dis-

**TABLE 1**

**The largest aquaculture industries, by volume, in 1999**

Values are in million metric tons

Species	Volume
Giant tiger prawn	3,651,782
Pacific cupped oyster	3,312,713
Japanese kelp	3,023,240
Silver carp	2,837,420
Grass carp	2,743,194
Atlantic salmon	2,448,280
Japanese carpet shell	2,194,521
Roho labeo	1,493,884
Rainbow trout	1,350,168
Japanese amberjack	1,282,090
Yesso scallop	1,252,448
Nori	1,249,923
Whiteleg shrimp	1,062,774
Nile tilapia	1,025,739

eases and movement of those diseases contribute to the volatility in production. Inevitably, as new aquaculture species are brought into culture settings, new diseases are identified that were previously unknown. In the past ten years, new viral diseases have been identified in shrimp and salmon, both of which caused large-scale losses from production facilities.

Of the approximately 25 mmt of global aquaculture production, there are only a few industries that produced over 1 mmt in 1996. Several of the species of Asian carp and the common carp account for the largest industries. Silver carp production was 2.2 mmt, grass carp production was 1.8 mmt, bighead carp production was 1.1 mmt, and common carp production was 1.5 mmt. Virtually all of this production occurred in China with the exception of common carp, which is raised throughout Europe, its native range. Of the species typically available in U.S. markets, pen-raised Atlantic salmon accounted for 0.4 mmt, rainbow trout production for 0.3 mmt, channel catfish production for 0.2 mmt, and tilapia for 0.6 mmt. Production of several invertebrates was significant. Scallop production was 1.0 mmt, shrimp production was 0.9 mmt, oyster production was 1.1 mmt, mussel production was 1.0 mmt, and clam production was 1.0 mmt. Production of brown seaweeds was 4.5 mmt and red seaweed production was 1.6 mmt. Thus, the largest aquaculture industry is the production of brown seaweeds, largely for nonfood use. In the twenty-first century, greater demand will likely result in increased production.

There are only a few production systems in use for aquaculture, and they include earthen ponds, raceways, cages or net pens, and indoor recirculating systems. Earthen ponds or cages placed in existing bodies of water are the oldest production system and the indoor recirculating systems are the newest. For successful culture, considerable technical expertise is required when us-

Fish culture technicians working in a fish hatchery in the early spring. PHOTO COURTESY OF UNITED STATES DEPARTMENT OF AGRICULTURE.

ing a recirculating system. All of the current industries use earthen ponds (catfish, tilapia, Asian carps, shrimp), raceways (rainbow trout), or cages/net pens (Atlantic salmon, yellowtail, an amberjack from Southeast Asia). Producers are experimenting with indoor recirculating systems using a wide variety of species. There are a few successful producers using indoor systems, but the number will inevitably grow as both the systems themselves and information on targeted species increase. Successful aquaculture can be viewed as the correct match of species under a certain set of market conditions with production system. Some species do not tolerate some of the production systems or do not thrive in those systems. Behavioral characteristics of the various species often point toward the appropriate culture systems. For example, sedentary fish (bluegill, catfish, and flounder) should probably be raised in systems without significant water flow (earthen ponds, cages/net pens), whereas those that typically swim a great deal (tuna, trout, and striped bass) can be raised in raceway systems with a constant flow of water.

Fish are generally considered good quality food for human consumption because of the low saturated fat levels and generally high levels of n-3 fatty acids. Fish tend to retain the fatty acids that are in their diet. Thus, we can manipulate the fatty acid concentrations of fish and produce “designer fish” for targeted markets. Further, we can control the fat concentration in muscle through selected feed and produce a low-fat or high-fat fish depending on the demands of the market. Cultured aquatic animals can be safer products for consumption than wild fish because they are raised in a defined environment, and pollutants can be eliminated. Wild fish can be exposed to environmental pollutants and retain those they encounter. Organoleptic properties (taste) of fish and shellfish raised in aquaculture can be quite different from wild stocks. Fish flavor can be manipulated by dietary ingredients fed to the target species. If the diet contains a rel-

atively high percentage of fish meal, the fish can taste fishier than if the diet contains a relatively high percentage of corn and soybean products. Fish fed the latter diets are often described as “milder” tasting, which is a desirable characteristic in certain markets. There is also a taste consideration with environment. Some species can survive both fresh- and saltwater, but osmoregulation changes to meet the challenges of those environments. This physiological change affects taste because of the chemical compounds used to regulate ionic balance. A good example of this is the freshwater shrimp. When raised in freshwater, taste has been described as mild, whereas if the shrimp is placed in saltwater for one to two weeks, it will taste more like a marine shrimp. Even with these positive attributes, aquaculture is experiencing growing pains.

Culture of aquatic animals produces the same wastes as other animal production industries. The problem is confounded by the fact that those wastes are discharged as rearing water is renewed. There have been incidences of environmental degradation resulting from aquaculture. One of the focal points of aquacultural research is waste management, focusing on phosphorus and nitrogen dynamics originating in the diet. Those efforts, as well as efforts related to siting aquaculture operations, land-use practices, and economic development, have become the focal point of sustainable aquaculture development. Along with the overall focus on sustainability, there are significant concerns about the feed used to achieve aquaculture’s successes. Fish meal is a high-quality ingredient, yet it is a finite resource similar to all other species in the oceans. Ingredients made from soybeans, corn, canola, wheat, legumes, peanuts, and barley, as well as the by-products of the brewing industries and animal packing operations, are needed.

Growth of aquaculture in the twenty-first century will most likely be similar to growth in terrestrial animal production seen in the twentieth century. Fish and shellfish are the last major food item humans still hunt and gather from wild populations. The sustainable nature of aquacultural production probably will be the focal point of research in the early part of the twenty-first century and those results should facilitate the production increases necessary for sufficient quantities of fish and shellfish in the future.

**ARCIMBOLDO, GIUSEPPE.** Giuseppe Arcimboldo (also spelled Arcimboldi), was an Italian artist in Milan, Italy, between 1527 or 1530 and 1593. A painter, he also designed the stained glass windows for Milan's duomo. Arcimboldo's artwork, especially famous for its fragments of landscapes, flowers, herbs, vegetables, noodles, and cookware, was fashionable during the sixteenth century. His work became especially well known throughout Europe after the Austrian Holy Roman Emperor Rudolf II exhibited Arcimboldo's paintings in the many residences of the Habsburg imperial family. In fact Arcimboldo's bizarre pieces and grotesque portraits pleased the Habsburg emperor so much that he appointed the Italian painter Habsburg court painter at Vienna and Prague and also made him a count palatine. Arcimboldo also created the illusionistic sceneries for the Habsburg court theater.

Arcimboldo's most famous paintings had contemporary allegorical meanings and were unique compositions of edibles and culinary objects placed together in such a way as to represent the contours or heads of cooks,

"The Waiter," an anthropomorphic assembly of objects related to winemaking by Giuseppe Arcimboldo. © CHRISTIE'S IMAGES/CORBIS.

innkeepers, fishmongers, and symbolic figures related to the world of arts and sciences. He was not prolific, but his paintings of fantastic heads and social satirical subjects were popular. Many surrealists, including the Spanish artist Salvador Dalí, claim Arcimboldo as a surrealist ancestor.

Arcimboldo's paintings and drawings in Austria are in Vienna's Kunsthistorisches Museum, in Graz, and in Innsbruck's Habsburg Schloss Ambras. In Italy his works are preserved in Cremona, in Brescia, and in Florence's Uffizi Gallery. In the United States the Wadsworth Atheneum in Hartford, Connecticut, houses some of Arcimboldo's work.

**ARCTIC.** The Arctic lies north of 70° latitude, marked by the tree line of the Subarctic. Few cultural groups occupy the Arctic: the Inuit live across the circumpolar region from northern Siberia throughout Greenland; the Aleuts and Yu'pik live on the coast and

islands of southwestern Alaska; and six major Saami groups live in the northern reaches of Scandinavia and western Russia. Arctic diets are unique because animal products are staples and plants are seasonal supplements. Inuit diets traditionally are composed of marine mammals, fish, caribou, small game, birds, and plants, while Saami depend on herded reindeer for milk and meat, fishing, gathering plants, and hunting small game and birds. The diets of Aleuts and Yu'pik are similar to that of the Inuit.

### **Inuit Food Lists and Categories**

Inuit are famous for eating marine mammals, mostly seal (*natsiq*). Bearded seal (*oodguk*), walrus, polar bear (*nanuk*), narwhal (*tuugalik*), beluga (*qilalugaq*), and the large plankton-eating whales are preferred foods. Seabird, goose, and duck eggs (*maniq*), ptarmigan, ducks, and geese are also eaten. Arctic char (*iqaluk*), an anadromous fish, is preferred above sculpin (*kanuyak*) and cod (*oogak*). Shellfish are consumed, but are not a major food resource. Land mammals, caribou (*tuktu*, or reindeer), and Arctic hare are eaten to achieve a culturally desirable balance in the diet. Commonly eaten plants include kelp, sorrel, willow, blueberry, crowberry, soapberry, winter-green, lichens, Eskimo carrots, and Eskimo peanuts. The vegetable matter from herbivore's stomachs is also consumed.

Animal foods are divided into those associated with the sea or ice and those associated with the land. Inuit are subsistence hunters and divide themselves into two categories, *Sikumiut* are "people of the ice" and *Taramiut* are "people of the land." These categories relate as well to hunting on the sea and on the land. For a community to maintain an ecological balance in the animals, subsistence rules are practiced. One rule is that, whenever possible, hunters seek to provide a mixed diet with animals of the sea and animals of the land. If this balance is not maintained in hunting, it is believed that the animals may disappear. Some years the seal are more prolific and available, so more seal is eaten. Other years more caribou or char will be abundant and consumed. The diet reflects this balance among land and sea animals. Hunters carefully respect the animals by maintaining the balance and thus ensure their future harvests. Plants are considered separately in the diet as treats that complement the standard animal fare when they are available. The most culturally desirable diet of the Inuit varies by mixing sea mammals, caribou, and Arctic char. The relative proportion of these three staples in the diet depends on the geographic location and local foraging practices of the group.

During the contact periods, European dry and canned staples were introduced as trade items across the Arctic. These new foods were slowly adopted into the Inuit diet. Foods became divided into two categories, "country" or foraged food produced by Inuit themselves, and store-bought or imported foods, obtained by trading furs or for cash. Common store-bought foods include tea,

sugar, flour, biscuits, and breads. Other imported foods include canned fruit and jam, meats, fish, and vegetables. Store foods are considered inferior and incapable of sustaining health for anyone raised eating country food.

***Meal customs and food distribution.*** Hunting and food sharing form the core of Inuit society. When hunters return with fresh game or fish, it is distributed for consumption according to social rules. This occurs at least several times a week. Meals are communal and all animal foods are shared, distributed first within the community and then within the household. During the distribution, fresh, or uncooked, meats are eaten by anyone who is hungry. The remaining portions are distributed according to the kinship or friendship relationship of the receiver to the hunter. The hunter, his wife, father, mother, or a related elder conducts this process. While this food remains in the household, family members eat it communally at least once a day.

The typical traditional meal includes fresh, boiled, fried, or grilled meats, organs, and soft bones. The food is served on the ground outdoors or on the floor of the shelter. The animal food is cut away from the butchered carcass with the personal knife of the individual and eaten without any other utensils. If the animal food is boiled, its broth is drunk after eating the meat. Everyone is expected to eat until hunger subsides. All visitors to a home are expected to partake of whatever game is available. Hoarding or overeating food is not acceptable. Birds, eggs, plants, and small fish or shellfish are usually eaten by individuals, but are shared on demand with anyone who is hungry.

As a result of contact with Europeans, drinking heavily sugared tea and eating bannock or some form of bread has come to follow the consumption of animal food. The bannock is made from flour, water or milk, and fat (lard, vegetable shortening, or caribou or seal fat) and baked on a rock or in a frying pan over a fire. Tobacco is then shared. Before black tea was introduced, herbs were collected for making teas.

Meal patterns are guided by hunger and age. Young children and babies are fed frequently on demand until they reach five or six. The adult demand for food varies, but fewer meals are eaten in winter than in spring, summer, and fall. On average, one full meal and two or three tea breaks are taken between sleeping. Elders eat less as they grow older, but drink sweetened tea more often. Immature seal, cached meat, and fish are favored by the very old individuals.

Men, women, and children eat together. The men eat with long knives (*sevik*) as they squat near the animal food, and women use the *ulu*, the traditional curved knife of Inuit women. Children use smaller versions of adult knives as soon as they can control them. Older infants and toddlers eat premasticated foods from their mothers, but are typically breast-fed until they are four or five. Orphaned or adopted babies are fed seal broth.

**Food preparation.** Food preparation varies by season and environment. At camp, Inuit share the communal feast daily. “Fresh” (uncooked) seal (*mikiayak*) or other marine mammals are prepared within a short time after the animal is captured. Camp dwellers are called by children to the feast. The hunter or a designated relative, typically his wife, opens the animal after the body has had time to “cool.” Those who are feeling cold would eat first, as the rich blood (*auok*) and warm chunks of exposed liver (*tingook*) warm the individuals’ bodies and restore health and well-being. The blood not consumed is drained and

the animal gutted. Organ meats, especially kidney (*taktu*), are eaten or fed to dogs along with the fat scraped from the skin and other waste. Intestines are saved, and the outer covering chewed. A delicacy among the North Baffin Inuit is chopped fat and brains mixed with the animal’s blood (*allupiauoq*) in the body cavity before the meat is eaten. Eyeballs are sucked but not swallowed. The skin is saved for household and clothing use. During hungry periods, when animals are scarce, the skin, scraped on both sides, can also be eaten. Seal “hips” are preferred by men in the Eastern Arctic, while women enjoy the tenderloin

along the spine, the backbone, and the ribs. Shoulders, flippers, and forelimbs are eaten by both men and women.

Marine mammals can also be eaten frozen (*quok*), sliced thin as the individual eats from the carcass, or the meat can be aged. To prepare aged seal, for example, seal is packed in its skin and stored a few days or as long as three weeks. Rotted seal is cached in the fall for consumption the next spring or summer. *Ooyuk* is soup made by boiling meat in fresh water, and seasoned with kelp. Salt or dry soup mix often replaces kelp. Chunks of meat are eaten out of the pot, which is usually set over a seal oil lamp or an open hearth. Cupfuls of rich broth (*kijuk*) are drunk. Seal is deep-fat fried in the summer or grilled on flat rocks over heather fires. Seal oil is produced by pounding the fat. This rendered oil is then stored in a seal bladder to be eaten with plants or raw or dried fish. In spring and summer, foods are cooked on heather fires, which gives them a wonderful herbal taste. Polar bear and walrus were once consumed fresh, or raw, but they are only eaten cooked, due to concern about Arctic trichinosis. Narwhal and beluga whale are prized for their sweet skin (*muqtuq*). The meats of these animals and other whales can also be eaten prepared as other meats are. Polar bear organ meats are never eaten.

While seal typically dominates the diet, caribou (*tuqtu*) is also widely consumed, prepared in ways similar to the seal. Caribou meat is also cut into pieces and hung to air-dry for storage. Birds are captured, their feathers plucked, and then eaten uncooked. Eggs are sucked. Arctic hare is boiled as *ooyuk*, never eaten uncooked. Arctic char are eaten fresh, filleted into three boneless pieces hung from the head, or partially air-dried (*serata*) or freeze-dried (*pisit*). The fish can be boiled as *ooyuk* or fried (*satoya*), or grilled as well. Shellfish are eaten raw or boiled, but are rare in the Eastern Arctic.

**Seasonal variation.** Seal, walrus, and polar bear typically dominate winter foods. *Ooyuk* is popular in winter, as are frozen foods. As the sun returns daylight to the land, spring begins and groups of related Inuit begin to congregate for camping and hunting seal. Short hunting trips include fresh seal picnics. Easter is marked by the spring caribou hunt and feast. Once the ice begins to break up, Inuit cannot travel safely. Whatever foods can be captured near land-based camps are eaten. When dried caribou, fish, and cached marine mammals are exhausted, the diet is aged seal oil with plants and, perhaps, fresh fish. Summer continues with full daylight, marked by open-water sealing and whale hunts, and *muqtuq* is prepared and consumed. Summer fish camps produce large numbers of char to eat fresh, frozen, or dried. Plants are gathered during long walks, mostly by women and children. Seal and caribou are fried and grilled. In August, the sun begins to leave the northern sky and early fall begins. A fall caribou hunt culls the migrating herds. Bulls are especially desired because of their rich fat. The quiet winter season returns and the annual cycle begins again.

## Foods of the Saami

Saami occupy the Arctic and Subarctic. These people were colonized in the thirteenth century and little is known about their indigenous foodways prior to colonization.

Saami lived traditionally by following the herds of reindeer seasonally as the animals fed on lowland lichens and mushrooms in early spring and winter and highland grasses in summer. The bulls were culled from the herds in October, December, and January to provide meat for fall and winter feasting and storage by smoking and drying.

Saami, like Inuit, eat caribou, or reindeer, using all the edible parts of the animal. Like the Inuit, they eat their foods cooked, boiled, smoked, and roasted. Reindeer meat is boiled in a thick soup that resembles Inuit *ooyuk*. Meat is eaten out of hand from the pot and the gravy scooped up in a cup to be drunk. Saami drink reindeer milk and use it to make cheese, which is often smoked, something Inuit do not do. While some Saami are known for reindeer herding, other groups and frequently eat fish. Both Saami groups, however, consume fish, land mammals, plants, and birds. Saami diets have been greatly influenced by northern European cooking patterns and foods for the past seven hundred years.

### FILM AND TELEVISION

Food has been a popular and versatile film prop since the silent film era. It's a perfect cinematic prop—simple to prepare, readily understood by the viewer, and able to provide countless ways to move a story line along and advance the theme of a film, be it political, sexual, interpersonal, historical, or even mystery. At times food plays a supporting role enabling the main character to further the plot. At other times food itself plays a starring role.

The first and most enduring food prop is probably the pie, largely because it is easy to make and easily aimed at a person we don't necessarily want to hurt but whose dignity is at stake. According to Lorna Woodsum Riley's *Reel Meals Movie Lover's Cookbook*, Mabel Normand launched the first pie in film when she spontaneously threw someone's custard cream pie at Fatty Arbuckle in a Keystone Studio silent film, *A Noise from the Deep* (1913). This act garnered lots of laughs so Keystone studios, under the direction of Mack Sennett, repeated it in numerous other films, as did such silent film stars as Laurel and Hardy, Buster Keaton, the Three Stooges, and Charlie Chaplin. Blake Edwards, in an homage to the silent era, placed Tony Curtis in the midst of an enormous number of flying pies in *The Great Race* (1965), and Nora Ephron in *Heartburn*, her semiautobiographical novel that was made into a film in 1986, tells her philandering husband just what she thinks of him by squishing a Key lime pie in his face.

Pies weren't the only food used in early films. Laurel and Hardy were major advocates of food in film, as best revealed in *A Swank Dinner Party*. Since they were the waiters at that party, it was, of course, anything but

swank. Hardy slips on a banana peel while carrying a huge cake, and even the swanky guests wreak havoc trying to nab the cherry in their fruit cocktail.

The scenes most remembered in some films are those in which food has played a supporting role. In *The Gold Rush* (1925, reedited in 1942) writer, director, and star Charlie Chaplin best demonstrated the dramatic possibilities of food. Finding himself freezing, starving, and snowbound in an Alaskan cabin with another prospector at Thanksgiving, Chaplin is unwilling to spend the holiday without an appropriate meal. So he boils one of his boots, carves and delicately plates it, offers his companion the choice of "sole" or "boot," and proceeds to eat the shoelace as though it were spaghetti. Simultaneously funny and touching, it is the film's most remarkable scene. Chaplin used food to make a political statement in *Modern Times* (1936) by showing the plight of the worker, in this case an assembly-line worker, and the heartlessness of management. To speed things up, a robot is devised to feed workers so they can continue working. In a hilarious scene Chaplin is given a meal of soup and corn on the cob by a robot that eventually runs amok.

The seduction scene in the Oscar-winning *Tom Jones* (1963) created a big stir because of the way in which food was used in an overtly sexual manner. Albert Finney, at his best as the womanizing Tom Jones, seduces actress Joyce Redman whom he has just met. Dining together, they consume chicken, oysters, and wine in a manner that grows more deliberate and increasingly sensual.

Woody Allen used food in *Annie Hall* (1977) to illustrate the cultural and ethnic differences of the film's protagonists. Midwestern WASP Diane Keaton is shown ordering a pastrami sandwich on white bread with mayo and tomatoes—a shock to Allen's New York Jewish character (pastrami sandwiches are always on rye with mustard). In *Five Easy Pieces* (1970), restaurant dining was difficult for Jack Nicholson, who had to use convoluted means just to get some toast, while Meg Ryan in *When Harry Met Sally* (1989) dictated in no uncertain terms exactly the way she wanted food served to her during lunch in a deli with Billy Crystal. This same dining scene also provided the perfect background for the film's most memorable scene—the fake orgasm.

Food and murder occur in equal proportion in Mafia movies. Francis Ford Coppola used lots of food in the first (1972) and third (1990) installments of *The Godfather*. Marlon Brando playing Don Corleone is shot while choosing fruit at an outdoor stand. And, after a rubout, Clemenza shows his priorities when he tells his partner "leave the gun, take the cannoli." Later Clemenza shows young Michael Corleone how to cook spaghetti with meatballs and sausage just in case he goes to jail and needs to know how. Near the end of the third *Godfather* film, Eli Wallach as Don Altobello waxes nostalgic about the virtues of olive oil just before he dies from eating a poisoned cannoli.

Director Martin Scorsese in *GoodFellas* (1990) presented a jail scene with actor Paul Sorvino carefully slicing garlic with a razorblade while a cellmate is preparing spaghetti sauce with beef, veal, and pork. Also on the menu are bread, cheese, prosciutto, steak, salami, peppers, and onions. This well-fed group of Mafia jailbirds sits down to eat a lavish meal with Frank Sinatra crooning in the background. Scorsese also showed he could film elegant dining. In *The Age of Innocence* (1993) there is a well-researched banquet scene resplendent with a floral and ice sculpture centerpiece, elaborate English bone china and silver tableware, impeccable service, and restrained table manners reflective of the late 1800s. The diners enjoyed oysters, fish, and other perfectly presented delicacies.

A septet of films has had particular success in casting food in a starring role. First among them is *Babette's Feast* (1987). Drawing from Isak Dinesen's short story, Gabriel Alex directed and wrote the screenplay for this Oscar-winning best foreign film set in nineteenth-century Denmark. Two adult sisters, the daughters of a pastor, live in a remote village where they have dedicated themselves to the service of God and relinquished all worldly desires. Babette, played by Stéphane Audran, is a French political refugee who is taken in by the sisters in return for working as their housekeeper and cook. Their meals consist largely of a humble gruel of bread soaked in ale. Some years after Babette's arrival, the sisters decide to hold a dinner to honor the hundredth anniversary of their father's birth and ask Babette to cook. She has recently won the lottery and sends her nephew to Paris to collect the necessary ingredients. Unknown to the sisters, she is a former chef, and she cooks for the sisters and the members of their little church the best feast ever shown on film. It begins with Potage à la Tortue, followed by Blini Demidoff aux Caviar Russe, Caille en Sarcophage avec Sauce Perigourdine, La Salade, Les Fromages, Baba au Rhum et Fruits Confit, Champagne Veuve Cliquot 1860, Clos de Vougeot 1845 wine, and coffee. Although her humble and religious diners had vowed to remain unaffected by the food, they are quickly overwhelmed by the mastery of this culinary artist who forever changed their lives.

*Tampopo* (1986), kind of a spaghetti western with a culinary theme, which was directed by Juzo Itami, demonstrated Japan's seriousness about food. Tampopo, a widow with a son, seeks the recipe for the perfect noodle to serve in her restaurant. Assisted by a truck driver who would have looked more comfortable on a horse, there is much intrigue along the way to noodle perfection. What makes this such a good food movie is the inclusion of a series of unrelated but very smart food vignettes ranging from sexual seduction to a lesson in the proper way for the Japanese to eat Italian noodles.

Taiwanese writer and director Ang Lee serves up a multitude of enticing dishes in *Eat Drink Man Woman* (1994). The film opens with five minutes of master chef

Charlie Chaplin in the 1925 movie *The Gold Rush* demonstrates the art of eating a boiled shoe. © BETTMANN/CORBIS.

Chu, played by Sihung Lung, chopping, dicing, steaming, and frying in what is, to date, the best sequence of food preparation on film. Chef Chu, a widower with three grown daughters, tries to keep his family together by serving sumptuous Sunday dinners. He prepares enormous meals including steamed deer spareribs with ginger in a pumpkin pot and lotus flower soup plus one hundred other dishes all prepared for the film by famous Taiwanese chefs. Lee said he had to shoot each dish within eight seconds to capture perfect steam, a requirement he found very stressful.

*La Grand Bouffé* (1973) is a French film in which four men gather at a country house to eat themselves to death with fabulous food prepared by one of them who, fortunately, is a chef. A nonstop display of gorgeous food both cooked and uncooked includes the best wild boar, lamb from Mont-Saint-Michel, oysters, calves' heads, cod, beautiful pâtés, tarts, quail on skewers, pastas, pizzas, pullets, and pigs to name just a few. This film is an amalgam of beautiful food, ongoing sex, and a dismaying array of bodily reactions to too much food. Although it remains unknown why these four successful men want to eat themselves to death, the film does portray the horrors of excess. A food credit is given to the French store Fauchon.

Master chef Paul Bocuse is credited for the beautiful food in *Who Is Killing the Great Chefs of Europe?* (1978), a whodunit filmed in some of Europe's best restaurants. Worth viewing just to see Robert Morley play Max Vandevere, the disdainful and pretentious editor of *Epicurious Magazine*, the film portrays the trouble that begins when he selects four chefs to prepare a dinner for the queen of England. Jealousy sets in, murder ensues, and chefs are killed in the manner in which they prepare their

signature dishes. There are beautiful shots of baked pigeon en croûte, pressed duck, the fish market in Venice, and the interiors of legendary restaurants

*The Cook, the Thief, His Wife, and Her Lover* (1989) is a complex and beautiful film in every way. Directed by Peter Greenaway, each frame looks like a Dutch genre painting. Costumes designed by Jean Paul Gaultier and a haunting musical score add to the film's lavishness. Here food provides the basis for magnificent still life frames while the lush red restaurant and eerie kitchen provide ongoing tableaux and the setting for a story about a loutish thief who thinks that dining in a fine restaurant elevates him to a higher social class. Not all is beautiful, however, in this film that also portrays denigrating sex scenes and cannibalism.

Laura Esquivel's novel *Like Water for Chocolate* (1993) was written as a prelude to a screenplay and includes recipes. In the film, directed by Alfonso Arau, Mexican family food is the star, and much of it has mystical properties that can start fires and evoke passion, sorrow, and uncontrollable yearning when it is cooked by the romantically unfulfilled Tita.

The decade of the nineties brought hefty expense accounts and ambitious restaurant dining in the United States. Coincident with this came three American films that explore restaurant life in remarkably different ways. *Big Night*, produced by Stanley Tucci in 1996, again explores the cook as an artist, much as *Babette's Feast* did, but within the difficult framework of cooking authentic ethnic cuisine in 1950s America. In 1998 Shari Springer Berman and Robert Pulcini directed a documentary entitled *Off the Menu: The Last Days of Chasen's*. Filmed just before the closing of the famed Los Angeles restaurant, it is a close look at a bygone era of Hollywood glamour when stars and movie moguls, dressed to the nines, made nightly appearances at their regular tables in this family restaurant where they were treated like valued family members and catered to in ways unimaginable in today's restaurant. *Dinner Rush* captured a very different restaurant scene, that of New York circa 2001. Directed by Bob Giraldi and shot in his own Tribeca restaurant, Gigino, *Dinner Rush* forthrightly portrays the downside of the restaurant business with its intrigues, food fads, trendiness, fickle customers, power struggles, critic corruption, and more. What with all of this, the film is edgy and fascinating and most likely tells it like it is.

## Television

Food in television has mostly been of the "how to" cooking show genre. Gerry Schrepf notes in *Celebration of American Food* (p. 99) that James Beard led the parade of cooking shows with weekly appearances in 1946, followed by Dione Lucas in 1947. Television pictures were black-and-white then, and only eight thousand homes had sets. Julia Child jump-started cooking shows with her 1963 inaugural series for public television, which was the leader in the production of such programs. Popular among view-

ers were the *Victory Garden* series and Jeff Smith as the *Frugal Gourmet*. Public television tends to feature cooking teachers and cookbook writers who are basically home cooks, creating food meant to be replicated at home. Capitalizing on an undeniable interest in good food, the genre catapulted to new and different levels when an entire cable network devoted only to food, the Television Food Network, was launched in November 1993, initially reaching three million homes and expanding to more than sixty million by the year 2002. The network experimented with a restaurant review show, a call-in show devoted to dieting and healthy eating, and, most notably, a one-hour live news show entitled "Food News and Views" that was, as its name suggests, devoted solely to the topic of food and drink. As the genre has matured, more attention has been given to the entertainment value of "cooking" shows, giving way to contests such as *Ready, Set, Cook* and Japan's entry, called *Iron Chef*, which features some unusual food video and involves a panel that judges the best dishes created during the time frame of the show. Attractive and youthful celebrity chefs have replaced home cooks on these shows, and celebrity food with refined ingredients and architectural presentation has replaced the homier presentations of earlier public television shows. A notably successful Food Network show has been that of Emeril Lagasse, whose catch phrases and natural good humor have made him its star. The Food Network, in turn, has given Emeril a live audience with which to interact, a band, and numerous other gimmicks to hold viewer attention. Martha Stewart became a television network cooking star in the late 1990s, combining her talents into a multimedia television, radio, cookbook, and magazine package.

Cooking shows are rarely done in real time. The standard format has the cook combining ready-to-cook ingredients, then going to a finished dish to show how it should look—which is usually splendid since television studios have state-of-the-art kitchens staffed with professional cooks and stylists who turn out elegant creations that either inspire or intimidate the viewer.

The History Channel broke new ground by presenting a series of documentaries entitled *America Eats: History on a Bun* (1999). More than just bun food, the histories of fried chicken, ice cream, soda pop, and pizza were explored with excellent use of archival footage showing how food and eaters alike used to look in America.

## LITERATURE

François Rabelais in his irreverent and influential sixteenth-century novel *Gargantua and Pantagruel* writes “[t]he satirist is correct when he says that Messer Gaster—Sir Belly—is the true master of all the arts. . . . To this chivalrous monarch we are all bound to show reverence, swear obedience, and give honour” (pp. 570–571). According to twentieth-century literary critic Mikhail Bakhtin, Gaster is portrayed by Rabelais not as the creator of society, but more as the embodiment of the organized human collective. Because appetite is located in the viscera, “[t]he bowels study the world in order to conquer and subjugate it” (p. 301).

What better place to begin a discussion of food in literature than with Rabelais’s novel in which references to food appear on nearly every page. This novel pokes fun at the sanctimoniousness of the hierarchy of the Catholic Church and the feudal elite by drawing on the humorous and vulgar language of the marketplace and the carnivalesque imagery of clowns, fools, giants, and dwarfs that were an integral part of medieval society. In carnival, the social hierarchy of everyday life is leveled, and individuals become united in a festival in which all participants are actors, and communal laughter mocks everyday society.

It is the belly and its appetites that give rise to the festival, and feasts of course inevitably accompany any festival. Such feasts celebrate the human encounter with and triumph over the world, in which food represents the entire process of cultivation, harvest, storage, trade, and preparation. Humanity devours the products of nature without being devoured by the world. This encounter takes place in “the open, biting, chewing, rending mouth” during carnival festivities (Bakhtin, p. 281).

Because of the excesses characteristic of celebratory feasting, Rabelais portrays his larger-than-life characters as capable of devouring much more than was humanly possible. Listen, for example, as the giant Pantagruel calls forth a feast for his men—with their grotesque bellies and wide-open throats—after a military victory in which only one opponent survived:

He had refreshment brought and a feast spread for them on the shore with great jollity; and he made them drink too, with their bellies to the ground, and their prisoner as well . . . except that the poor devil was not sure whether Pantagruel was not going to devour him whole; which he might have done, so wide was his throat . . . and the poor fellow, once in his mouth, would not have amounted to more than a grain of millet in an ass’s throat. (p. 250)

Food imagery in *Gargantua and Pantagruel* is just one of the more extreme examples of the feast in literature.

The jovial, celebratory feast, the culmination of the process of growing food, in which humankind in social solidarity encounters the world with an open mouth, naturally gives rise to excellence in conversation, to wise speech, and therefore to literature.

In Plato’s *Symposium*, for example, a group of prominent Athenians gather to discuss the nature of love over an elaborate meal, during which Socrates is both lauded for his wisdom and mocked for his homeliness. The feast also is a celebration and validation of a community, and a celebration of victory, such as a successful marriage, military victory, or treaty. Feasts, therefore, bring to a close several of Shakespeare’s romantic comedies, such as *As You Like It* and the *Tempest*.

In Fielding’s eighteenth-century novel *The History of Tom Jones, a Foundling*, for example, the hero’s general lust for life is portrayed through his appetite for food and sex together. In the nineteenth century, when Victorian British society developed ambivalent feelings toward human appetites in general, Charles Dickens portrays one of his best-known characters, Oliver Twist, being thrown out of an orphanage for having more of an appetite than the authorities deem fitting.

## Food in Culture and Memory

Feasts and food in literature, however, portray more than the mere physical appetite for food and a human triumph over nature in festivals. Each culture, with its own tradition of literature, also maintains its own distinct cuisine and distinct traditional rules that govern acts of eating. The food traditions of a community are composed not just of recipes, but of the methods and technologies by which foods are grown, gathered, stored, prepared, served, and thrown out. Such traditions include also culturally transmitted rules that govern ideas of health and cleanliness as related to food. Furthermore, each community that gives rise to a distinct literature necessarily also maintains culturally specific rules governing foods that are especially valued and foods that are especially shunned and controlling the contexts in which particular foods may or may not be eaten.

In events that involve the serving of food—from snacks to meals to festival feasts—networks of reciprocity among food preparers, as well as the relationships between those doing the cooking and those being served, become articulated. Food and events in which food is served, therefore, help define the social organization and cultural identity of the very communities that give rise to distinct literary traditions.

Because food customs call forth such a labyrinth of associations on the part of individual writers, and because the inherent sensuality of food involves not only the senses of smell and taste, but also the other senses, food is capable of evoking an avalanche of memories and feelings. Food imagery may appear, therefore, in literature as a source of deeply embedded associations that lead into

the depths of individual and cultural memory. Perhaps showing the influence of Freudian thought, Marcel Proust's *In Search of Lost Time* (commonly known as *Remembrance of Things Past*) evolves from the narrator's memories brought out of the unconscious and into his conscious mind as he ate crumbs of "squat, plump little cakes called 'petites madeleines,'" that he had dipped in a cup of tea:

And soon, mechanically, dissipated after a dreary day with the prospect of a depressing morrow, I raised to my lips a spoonful of the tea in which I had soaked a morsel of the cake. No sooner had the warm liquid mixed with the crumbs touched my palate than a shudder ran through me and I stopped, intent upon the extraordinary thing that was happening to me. . . .

Undoubtedly what is thus palpitating in the depths of my being must be the image, the visual memory which, being linked to taste, is trying to follow it into my conscious mind. . . .

And suddenly the memory reveals itself. The taste was that of the little piece of madeleine which on Sunday mornings at Combray (because on those mornings I did not go out before mass), when I went to say good morning to her in her bedroom, my aunt Léonie used to give me, dipping it first in her own cup of tea or tisane. (pp. 60–63)

### The Meal as Communion

Despite the availability of individual associations about food to a writer, it is the sharing of food within distinct food cultures that continues to be the major focus of literature about food. Furthermore, this sharing of food continues to be commonly portrayed in literature as a communion, even though the public festival of the late Middle Ages has, in modern society, become private. The famous Christmas feast that concludes Dickens's sentimental children's story, *A Christmas Carol*, with its flaming plum pudding and its transformation of the miserly Ebenezer Scrooge into a more generous soul, is a prototype.

The family dinner as a private religious festival is perhaps more clearly seen in Virginia Woolf's novel *To the Lighthouse*, in which a private dinner of *boeuf en daube* gives a well-housed coherence to an otherwise dark and fragmented world outside of the home. The cook and main character, Mrs. Ramsay, leads in this communion. In preparation, Mrs. Ramsay lights the candles,

and the faces on both sides of the table were brought nearer by the candlelight, and composed, as they had not been in the twilight, into a party round a table, for the night was now shut off by panes of glass, which, far from giving any accurate view of the outside world, rippled it so strangely that here, inside the room, seemed to be order and dry land; there, outside, a reflection in which things wavered and vanished, waterily. (p. 108)

Expanding on the idea of the meal as a private festive occasion, Woolf writes that Mrs. Ramsay serves the main course of beef:

And she peered into the dish, with its shiny walls and its confusion of savoury brown and yellow meats, and its bay leaves and its wine, and thought, This will celebrate the occasion—a curious sense rising in her, at once freakish and tender, of celebrating a festival. (p. 111)

A description of a fruit basket in the center of the table—the literary equivalent of a painting of a still life, writes Bettina Knapp, author of an essay about this dinner scene—concludes the description of the whole meal. The still shapes and the rich textures and colors in the basket of fruit represent, in peaceful form, the emotional complexities contained within the character of Mrs. Ramsay herself, and the serenity born of that particular meal.

Meals portrayed in literature as moments of light and warmth in the dark and cold are not uncommon. In Herman Melville's *Moby Dick*, Ishmael and Queequeg, the Fijian cannibal, share a meal of clam chowder in a jovial inn in cold and wintry Nantucket, Mass., just as they had shared a warm bed together earlier in New Bedford on a bitter New England night. Ishmael comments that to appreciate warmth it is best to feel as if you are "the one warm spark in the heart of an arctic crystal" (p. 48).

In perfect contrast to the social solidarity of the shared meal, Captain Ahab compares the life of isolation that he has led with the life of community that could have been his had he not been obsessed with the white whale. He states this contrast in the language of food as metaphor, and shared food—in this case, the breaking of bread—as communion:

When I think of this life I have led; the desolation of solitude it has been; the masoned, walled-town of a Captain's exclusiveness, which admits but small entrance to any sympathy from the green country without—oh, weariness! heaviness! . . . and how for forty years, I have fed on dry salted fare—fit emblem of the dry nourishment of my soul!—when the poorest landsman has had fresh fruit to his daily hand, and broken the world's fresh bread to my mouldy crusts . . . aye, aye! What a forty-years' fool—fool—old fool has Ahab been! (pp. 477–78)

### The Feast as a Focal Point of Plot

While plot in literature most often focuses on the vicissitudes of human relationships, on love, conquest, betrayal, and loss, rather than food, the feast—as both the culmination of one process and the beginning of another—naturally appears as a fulcrum on which plots can turn. Meals and feasts, then, often provide the framework for events. Meals that are not portrayed as placid communions, therefore, reveal the contradictions brewing in the plot. In Homer's *Odyssey*, it is just after a feast of the suitors, which the hero attends disguised as a beggar, that Odysseus announces his return and slaughters his rivals. In Shakespeare's *Hamlet*, the juxtaposition of the wedding of the bereaved queen too soon after the funeral of her husband elicits from Hamlet himself the ominous quip that "the funeral bak'd meats did coldly furnish forth

the marriage tables" (Act I, scene ii, lines 180–181). By juxtaposing two antithetical feasts, Shakespeare warns the reader that foul play, yet to be revealed in full, has taken place.

In *Beloved*, the 1987 novel by Toni Morrison, the central tragic episode of the story—an escaped slave's murder of her own young daughter to prevent her from being taken back into slavery—is immediately preceded by a feast that celebrates the young mother's freedom. This feast begins innocently enough when the man who ferried the woman across the Ohio River to freedom brings two buckets of blackberries to the family to be made into pies. To the pies, the family incrementally adds turkey, rabbit, fried perch, corn pudding, peas, various breads, and desserts, and invites the whole community to attend. "Ninety people . . . ate so well and laughed so much, it made them angry," Morrison writes (p. 136). They were angered that this family would celebrate so proudly while others still suffered. Yet the reader knows from the beginning that the celebration is premature and therefore doomed: the young woman's husband, the son of the older woman with whom she has come to live, remains in slavery and in danger. The plot turns from victory to tragedy on the fulcrum of the feast.

An excessive meal can betray other excesses latent in the personalities of the characters. In *Anna Karenina* by Leo Tolstoy, the characters Levin and Oblonsky share a meal that seems vulgar in its quantity. During this meal of three dozen oysters, *soupe printanière*, turbot with sauce Beaumarchaise, roast beef, *poulard à l'estragon*, parmesan cheese, *macédoine de fruits*, vodka, champagne, and two bottles of Chablis—a gustatory metaphor for Tolstoy's opinion of the excesses of nineteenth-century Russian aristocrats—Levin speaks of his desire to propose to a woman half his age. Oblonsky, who himself has just been caught being unfaithful to his wife, encourages him. The food and conversation at the table encapsulate the magnitude of human desire that Tolstoy lays out in his novel as a whole, and cautions of the price that all pay for seeking the satiation of their desires.

### Meals, Communion, and Counterculture in the American Novel

While in modern Western literature communion and meaning can be found around the dinner table, in the tradition of the American antihero, the bourgeois dinner table has sometimes been portrayed as stuffy and stultifying. Mark Twain perhaps began this tradition in *Huckleberry Finn* when he describes Huck complaining about having to abide by social manners at the Widow Douglas's house:

When you got to the table, you couldn't go right to eating, but you had to wait for the widow to tuck down her head and grumble a little over the victuals, though there warn't really anything the matter with them,—that is, nothing only everything was cooked by itself. In a barrel of odds and ends it is different; things get

mixed up, and the juice kind of swaps around, and the things go better. (p. 4)

Countercultural characters similar to Huck appear recurrently in American literature. In this tradition, the wild out-of-doors, away from the social conventions of the dinner table, engender their own religious sensibility. In its suspicion of conventional modernity, this countercultural sensibility relates to the conventional the way that the carnivalesque related to feudal culture. Sometimes this suspicion of the conventional can also be symbolized by food, by a countercultural communion of sorts.

Ray Smith in Jack Kerouac's *Dharma Bums* speaks of himself as a religious wanderer, hops a train going north from Los Angeles, and shares a counter-communion in the freight car with an old hobo:

The little bum was sitting crosslegged at his end before a pitiful repast of one can of sardines. I took pity on him and went over and said, "How about a little wine to warm you up? Maybe you'd like some bread and cheese with your sardines?" (p. 4)

The communion on the freight train ends with the little bum "warming up to the wine and talking and finally whipping out a tiny slip of paper which contained a prayer by Saint Teresa announcing that after her death she will return to the earth by showering it with roses from heaven, forever, for all living creatures." (p. 5).

Whether in a public festival, a private bourgeois home, or in a distinctly nonbourgeois boxcar, the sharing of food in harmony is indeed a blessing, as the saintly shower of roses ending this one literary meal indicates.

### Food and Social Healing

Finally, another strand of food literature in the United States is represented by *Dinner at the Homesick Restaurant* by Anne Tyler and *Home at the End of the World* by Michael Cunningham. In Tyler's work, Ezra, the youngest child of a broken home, opens a restaurant called Homesick Restaurant, where he fervently hopes the world's emotionally wounded will find healing in the nurturing environment of a restaurant that serves home-style cooking. In *Home at the End of the World*, a nontraditional family opens the Home Café in Woodstock, N.Y., hoping to offer the world honest, home-cooked food, when traditional fare has become so processed and standardized that it fails to meet the needs of a materialistic, spiritually bereft American nation.

## OPERA

Just as one cannot separate words and music to get at the mystery of opera, food and opera are more compelling together than they are apart. The most immediate connection between the two is at the mouth and throat. Singers are understandably focused on these areas and seek gustatory gratification as a means of dealing with preperformance jitters and postperformance elation and exhaustion. It is not uncommon for a singer to lose five pounds during a long evening of exertion while wearing a thirty-pound costume under hot lights.

Singers and audience members both have their dining traditions. Each tends to eat sparingly before a performance: singers to avoid feeling full (although Beverly Sills famously ate steak before going onstage) and opera-goers so that they will not doze off while digesting a large meal. At intermissions some audience members have a light snack and a refreshment. Singers will seek liquid refreshment during performances—Birgit Nilsson often had a beer waiting at the side of the stage to slake her thirst. American tenor Richard Leech chomps on ice cubes to keep his mouth and throat cool.

Following performances, there is—especially in Europe—a tradition known as "souper." This is late-night eating in which the food is more festive than gastronomically challenging. The idea is to continue the sense of occasion that a night at the opera can foster. At a supper meal, whether attended by musicians, audience members, or both, dishes might include smoked fish, boiled shrimp with piquant sauces, rollmops, broths, risotto or pasta with truffles and cheese, boiled beef, and cakes, all washed down with copious amounts of wine, beer, and, especially, sparkling wine. The goal is that the food be tasty and arrive quickly. The most famous operatic depiction of supper is in the second act of *Die Fledermaus* by Johann Strauss Jr., in which party guests dance, sup, and sing in praise of champagne.

It is not surprising that chefs vied to create dishes to honor singers, composers, and opera characters. While performing at Covent Garden in London, the famous Australian opera singer Dame Nellie Melba dined at the nearby Savoy Hotel where the French chef Georges-Auguste Escoffier created in her honor both a form of well-browned, very dry "Melba" toast and a dessert he called "Peach Melba," consisting of a poached peach covered with vanilla ice cream and a special raspberry sauce and a garnish of chopped pistachios. Escoffier also created Sole Othello, combining the dark hues of truffle and mushroom (for Othello) with the pure white fish (for Desde-

mona). Luisa Tetrizzini had her famous turkey and noodles, and Gioacchino Rossini (opera's greatest gourmand) lent his name to any dish that featured truffles and foie gras. Enrico Caruso loved chicken livers, so preparations that included them bore his name. Wagner, a vegetarian, did not inspire chefs. Nor did Beethoven, who resented having to periodically stop composing to seek sustenance.

Although many operas seem to have drinking songs and choruses (in part because singers willingly consume thirst-quenching beverages onstage), there are not many eating scenes for the simple reason that food would obstruct the singers' vocal equipment. Mozart's Don Giovanni, who satisfies many appetites in the course of the opera, does dine heartily in the second act, although most interpreters of the role mime eating and ingest very little. Puccini's Tosca plays with her food in the second act until she discovers the knife that she will use to kill Scarpia. The funniest eating scene in opera comes in Rossini's *L'Italiana in Algeri*, in which the Italian Isabella feeds copious amounts of spaghetti to Mustafà, her Algerian captor, to distract him as she engineers her escape. As she runs to a ship in the harbor, Mustafà is dutifully twirling his pasta as he has been instructed. Surely the mezzo-soprano, once the curtain falls, will seek a bowl of noodles all her own.

### PAINTING AND THE VISUAL ARTS

Within the purview of world cultures, the vast majority do not address the subject of food in art in a gustatory manner or, at least, not to any great extent. When the subject emerged in the Mediterranean Basin, it was the Italians—one of whose bequests was the very concept of *civitas* (or civilization)—who have had the longest history of a preoccupation with food. This being said, all art about food for eating in the West can be divided into three parts: leftovers on the floor, food displayed in preparation for the meal, and completed dishes, whether cooked or ripe, set out on a table, ledge, or some other flat surface. The ancient Greek beginnings were preserved by the Romans and feature the *rhōpoi*, the trivial remains of a meal found in a floor mosaic that call to mind the excesses imagined by Petronius for the feast of the ex-slave Trimalchio in the *Satyricon*. Alternatively, there is the *xenion*, the gift of food laid out on a ledge and painted on the wall in trompe l'oeil to tempt and tease a tired traveler.

With the establishment of Christianity as the official religion of a declining Roman Empire, secular subject matter went into eclipse. However, there was still

food on the table in the proper sanctified contexts, such as the *Feast in the House of Levi*, the *Wedding at Cana*, *Christ in the House of Mary and Martha*, the *Last Supper*, and the *Supper at Emmaus*. Medieval renderings of these subjects feature food only in its rudiments. But from the Renaissance through the Baroque periods, there is a resurgence of worldliness, manifesting itself in a considerable interest in the menu and the table setting. Tintoretto's *Last Supper*, in the Church of San Giorgio Maggiore, Venice, is a case in point. Here, the serving of a wide range of foodstuffs by assembled servants distracts from Christ's proleptically offering the Host to his disciples. Another example is Veronese's huge *Last Supper* for the Monastery of Santi Giovanni e Paolo, Venice. Wine in large bottles, wrapped in leather or raffia, is poured into hand-blown Murano goblets. A large bowl holding fowl is set before Jesus; a mercenary walks away from the table with a plate full of food, tipping his head back to down his wine. Veronese even records that cutlery invention borrowed from Byzantium, the fork. When the Inquisition objected, Veronese pled artistic license, but changed the title to *Christ in the House of Levi*.

A very important entrepôt for the depiction of food and its cultivation is found in the calendar pages and borders of the Books of Hours of the early Renaissance. In the *Book of Hours* of Catherine of Cleves, the cooked, pricked biscuits and pretzels, and the raw mussels, a crab, and fish eating fish, border the images of individual saints. A notable instance of calendar events is found in the Limbourg Brothers' *Les Très Riches Heures du Duc de Berry*. In January, Berry sits at a groaning board to celebrate the Feast of the Epiphany; in September, the grapes are harvested at his favorite chateau. A second broadcasting of seed occupies a peasant in October, while by November, peasants are tasked with shaking down acorns to fatten the boars that will be consumed at Christmas. This tradition of seasonal occupations and festivities carried over into oil painting in the five great landscapes by Pieter Brueghel the Elder. His *Return of the Hunters* illustrates a perennial activity in the dead of winter, the slaughtering and singeing of a hog. Brueghel also essayed the novel subject of Carnival battling with Lent, who proffers the fasting foods of pretzels and herring on a peel in opposition to the skewered viands of gluttony.

In the secular realm, Renaissance Italy set the tone for the rest of Europe in art, in horticulture, in cuisine, and in prolonged, elaborate feasting that was both a political statement and a gastronomic assault. Paintings of interiors of vast noble kitchens filled with activity provide visual complements to the descriptions of state banquets set down by the professional cook Bartolomeo Scappi in his monumental *Opera* (1570). At the opposite end of the spectrum are the exquisite watercolors on parchment created by Giovanna Garzoni, many of them for the Medici, who were avid innovators in gardening. Frequently, her figs, broad beans, artichokes, or cherries, painted life-size, are set out in bowls lined with grape

Still life with artichokes in a Chinese dish by Giovanna Garzoni (1600–1670). Collection of the Pitti Palace, Florence. PHOTO COURTESY OF DR. PHOEBE LLOYD.

leaves that are placed on Mother Earth to honor the Tuscan preference for rustic food fresh from the land. A contemporary foil to Italy's gastronomic bliss is Anthonius Claesson's painting of an English family of ten saying grace at a table, where a roast of beef holds center stage framed by two great salts. There is a round loaf of bread on the table, but no vegetables, and an old-fashioned cut of bacon is being carried to the table.

It is this Italian absorption with food that prompted Annibale Carracci to invent the first genre paintings in the 1580s. Although he excelled as a history painter, Carracci departed from this exalted calling when he painted two scenes of meat stalls, where butchers were plying their trade, and another of a peasant *mangiafagiolo* (bean eater), mouth agape, hungrily shoveling in beans. Following on the heels of Carracci, the archrebel Caravaggio revived the *xenion* tradition in the 1590s with his *Basket of Fruit*. The fruit is piled high in a wicker basket that extends over a ledge. A similar basket of fruit at the table's edge graces his *Supper at Emmaus*, where the realism of the well-accounted table is balanced against the miraculous moment of Christ's revelation.

By the seventeenth century, the Dutch, whose country was arguably the wealthiest in Europe at that time, rivaled the Italians in prolonged feasting and in paintings about comestibles characterized by spillage and overabundance. That Dutch still life of the interrupted meal and genre paintings of market scenes and the stalls of fishmongers and butchers may be vanitas symbols or al-

legories of gluttony, or the five senses, respectively, is much debated. Whatever their symbolic charge, they, nevertheless, reveal what went onto the Dutch table and into the Dutch stomach. In stark contrast to these paintings that become touchstones for everyday experience is Rembrandt's depiction of the *Slaughtered Ox*, where the stilled life of the carcass, slit down the belly, splayed and hung, functions on the level of metaphor.

The Dutch and the Spanish, who were united under Habsburg rule until 1581, diverge in their depictions of food. Spanish art's distinctive contribution is the *bodegón*, where food is displayed on a ledge in stark raking light. The *bodegón* replicates the environment in which Spanish food was often placed, since in that hot Mediterranean country the kitchen was located in the basement with windows placed high in the wall. Outstanding examples of the *bodegón* aesthetic are found in the oeuvre of Sanchez Cotan, whose works have been rightly pronounced "solemn, magical larders." *Bodegóns* are for contemplation, not consumption.

The French, who from Gallic times had displayed an especial affinity for food's preparation, did not produce distinctive still lifes and genre paintings with foodstuffs until the eighteenth century. Then Chardin, whose subject matter so often addresses the domestic worlds of working-class maids and middle-class mothers, masterfully crafted works that reflected their domain in the kitchen and at table. Some of his still lifes can even be read as a list of ingredients that make up a particular dish.

*The Bean Man* shows an Italian peasant enjoying a bowl of beans. Painting in the collection of the Galleria Colonna, Via della Pilotta, Rome. REPRODUCED BY PERMISSION.

Concurrently, Boucher introduced the subject that was destined to become a French preoccupation, the *déjeuner*.

Although the Philadelphia still life painter Raphaelle Peale probably did not know the work of Chardin, he, too, assembled and painted raw ingredients for a meal. His other specialty was depicting a variety of skillfully decorated cakes. It is germane that, by the Federal era, Philadelphia was not only America's most culturally sophisticated and ethnically diverse city, but also her culinary capital.

On the Spanish front, the early nineteenth century witnessed Napoleon's Peninsular War and the retaliatory tactics of guerrilla warfare. In this brutal atmosphere, Francisco Goya also pursued the idea of still life as metaphor. His three gutted salmon slices, rendered a pulsating deep pinkish red, are not set forth in anticipation of a meal. The painting is about evisceration.

By contrast, there are numerous instances when it becomes clear that artists have been preoccupied with food's pleasures. The record goes back to Michelangelo. His illustrated list for a Lenten menu, though restricted to bread, fish, and wine, expands as he contemplates the happy possibilities. Not surprisingly, it is in nineteenth-century France, in the era when French haute cuisine was perfected, that the joys of the table begin to proliferate

in art. Renoir's *Luncheon of the Boating Party*, which takes place at the Restaurant Fournaise on an island that divided the Seine at Chatou, celebrates a meal that has advanced to the dessert course. Renoir's friend Monet was equally taken with the subject of mealtime; it is significant in this regard that at one point Renoir stole bread so that the Monet family would not go hungry. Early in his career, Monet depicted the *déjeuner* as it was consumed by family or friends on four occasions. Later in life, when Monet was established in his career and could afford to buy a house in Giverny, he would give special consideration to the interior decoration of the chrome yellow dining room, down to the detail of two sets of china. His cooking journals record what was placed on those plates. Bonnard is another French artist who depicted the pleasures of the table. Nor should it be forgotten that the painting that launched the Impressionist rebellion was about—and not about—lunch: Édouard Manet's *Le Déjeuner sur l'Herbe*.

Matisse helped usher in modern art by serving up the resplendent *Harmony in Red* (1908–1909). Against a red wall decorated with blue floral arrangements, a motif that flows onto a red table holding two wine decanters, fruit, and rolls, a maid bends slightly to arrange more fruit on a compote. A riveting instance of a Surrealist's preoccupation with food on the table is René Magritte's

1935 *Portrait*. Magritte's scene is set in a bistro with a bottle of wine and a place setting for one gracing the table. In keeping with his conviction that images are treacherous, Magritte fills the plate with a round slice of ham containing one centered eye looking up at the diner, hence the artist's title. Another Surrealist contribution is Meret Oppenheim's *Objet: Déjeuner en fourrure*, a fur-lined teacup and spoon that has become a veritable icon.

As the twentieth century progressed and people became more removed from food's involved preparation, art about food lost its celebratory aspect. Edward Hopper's *Night Hawks* (1942), though set in a diner, is hardly about the enjoyable consumption of food. Rather it excludes the grim impersonality found in film noir. As the availability of food came to be taken for granted on account of mass production, art about food dwindled into banality. Several 1960s Pop artists addressed the topic. Wayne Thiebaud's deliberately monotonous pies and cakes, so synthetic looking, are reminiscent of the days of the Automat. A further distancing of food from contexts of nurture and nature is found in Andy Warhol's obsession with highly commercialized processed food in his images of soup cans and bottles of Coke that unfold repetitiously. Claes Oldenburg's response was to transmogrify junk food. In 1979, Judy Chicago completed *Dinner Party*, a tribute to famous women that took the form of a particularized place setting representing each woman, the settings themselves laid out along the raised rim of a triangular table. It fell to a farm girl born in Sun Prairie, Wisconsin, in 1887, to hold to tradition. Although Georgia O'Keeffe never painted food and did not cook herself, she appreciated others who did and would prepare superbly the fresh, simple foods she relished; and she enshrined their recipes just as Monet or Alice B. Toklas had, by keeping a food journal.

#### POETRY

Food has been a topic of poetry for many centuries and in many cultures; the notion that food writing and poetry writing are totally separate ventures is a recent development. Much of our knowledge of eating habits, culinary practices, and food taboos throughout history and around the world comes from poetry. Food in poetry also functions as a powerful symbol of spiritual and moral states, and at other times it is used as a sexual symbol.

The Chinese have a long tradition of including food in poetry, going as far back as the Chou Dynasty (from the 12th century B.C.E. to 221 B.C.E.). There are Chou poems celebrating festive foods of the time, including stewed turtle, fried honey cakes, duck, quail, and good wine, and discussing the preparation of rice. The *Shih Ching* (Book of Songs) includes food scenes such as lamb sacrifice, in which the aroma of the roasting meat is described and fruit and wine are offered; verses on a feast of rabbit and plenty of wine; a song rejoicing in family togetherness at a feast including such meats as lamb, ox, and tripe, and an abundance of wine; agricultural songs celebrating wheat, millet, barley, plums, cherries, dates, melons, gourds, beans, garlic, and rice (from which wine is made). The culinary abundance of the T'ang Dynasty (618–907) is strongly evident in its poetry, which contains paeans to plums, pears, persimmons, jujubes, many kinds of melons, spring wine, and peaches, which were a traditional symbol of immortality in Chinese poetry and painting. Poems were also forums for discussing differences between foods. For instance, the eighth-century poet Chang Chiu-ling used poetry to address the many ways in which lychees and longans are not similar fruits at all, despite their superficial similarities. Poems written

during another prosperous period, the Ch'ing Dynasty (1644–1922), link food and sex, with female beauty and sexuality compared to melons, cherries, and grapes.

Food is also an important presence in classical Western poetry. Homer's *Iliad* and *Odyssey* are rich with scenes of feasting, as well as of ordinary eating. In a famous scene from the *Odyssey*, Odysseus and his crew, trying to return by sea to Ithaca, stop at an unknown land whose inhabitants, the Lotus Eaters, offer a lavish banquet to the three men who are sent to explore. The fruit (or the juice from the fruit) that the men consume gives them great pleasure and also makes them forget all thoughts of home and family so that the other crew members must drag them away by force. Homer also describes the feast of roast meat served to Odysseus by Achilles. The Greek poet Hesiod wrote about enjoying good wine with meat and bread. The Roman poet Martial wrote a great deal about foods, such as figs, olives, parsnips, chicken, fish, cheese, eggs, chives, shallots, and onions, to name a few. Virgil described milk and cheese in his *Georgics*, which celebrates the agricultural life and mourns the dissolution of Italy's farms after farmers were sent to war. Ovid wrote about olives and grapes in the *Amores*. In Greek mythology, the six pomegranate seeds eaten by Persephone (daughter of Demeter, goddess of agriculture) in the underworld after her abduction by Hades, are the mythical reason for winter: For each seed consumed, Persephone must spend a month of the year in the underworld, causing her mother to grieve and neglect her work. The story of Persephone and the pomegranate seeds continues to influence contemporary writers. In her collection *Mother Love*, the American poet Rita Dove writes of a modern young woman's journey to Paris that parallels Persephone's descent into the underworld. Her meal at "the Bistro Styx" includes Chateaubriand, Camembert, pears, figs, parsley, bread, and Pinot Noir. A mourning modern Demeter has a Spartan breakfast of cereal and raisins and puts stones into it.

Roman poets, including Catullus, Horace, and Martial, also wrote dinner-invitation poems. In the invitation poem, the poet cajoles the addressee into coming for dinner. He may describe the foods that are going to be served, talk about the wine that is going to be poured, and describe the entertainments that will be offered. Invitation poems are not only a source of information on what the Romans ate, but also literary documents in themselves. This tradition did not end with the Roman Empire. In the style of the classical invitation poem, Ben Jonson's "Inviting a Friend to Supper" describes a meal of salad, mutton, fowl, cheese, fruit, pastry, and wine. Another, more extensive food catalogue occurs in Jonson's "To Penshurst," which includes pheasant, carp, eels, cherries, plums, figs, grapes, quinces, apricots, peaches, cake, nuts, apples, cheeses, pears, beer, bread, and wine.

In the medieval Arab world, among those with sufficient resources, poetry and food were enjoyed in tandem, in lavish fashion. At banquets given by the caliphs,

## FOOD IN OVID'S *ART OF LOVE*

The Roman love poetry of Ovid (43 B.C.E.–17 C.E.) reminds us of the ways in which food can serve erotic or aphrodisiac purposes. He talks of signals exchanged between secret lovers across a dinner table, and of messages written with a finger in spilt wine. He imagines a rival carefully mixing wine for a girlfriend, selecting the tastiest morsels from a serving dish for her to enjoy (Ovid, *Amores*, book 1 poem 4, and book 2 poem 5; see Ovid, *The Erotic Poems*, translated by Peter Green, Harmondsworth and New York: Penguin, 1982).

Ovid makes fun of aphrodisiac foods in a tongue-in-cheek didactic poem on love and seduction, in which he conscientiously lists several of such foods that Romans believed to be effective:

Some old women will tell you to take dangerous herbs and salep (I judge these to be poisons), or they will mix for you pepper and stinging-nettle seed and pellitory chopped into vintage wine. But the Love Goddess . . . does not permit her pleasures to be forced in that way. You can try the white bulb that comes from Megara; try the lascivious rocket leaf grown in gardens; try eggs; try honey from Mount Hymettus; try the nuts that are found in prickly pine-tree cones (Ovid, *Art of Love*, book 2, lines 415–424. Translation by Andrew Dalby).

Salep is the ground root of an orchid (*Orchis mas* and other species) that is familiar as a hot winter drink in Turkey and the Balkans. Pellitory-of-Spain or Spanish chamomile is an ancient medicinal herb (*Anacyclus pyrethrum*). Rocket leaf (*Oruca sativa*) is the spicey-leafed plant arugula. The grape-hyacinth bulb (*Muscari comosum*), once a speciality of Megara in central Greece, is often served as an appetizer: it is known as *volvi* in modern Greek and *lampascioni* in Italian. Mount Hymettus, near Athens, is a source of fine honey.

Andrew Dalby

poems naming each dish—and recounting the spices and herbs used in its preparation, as well as the method of cooking—were recited during the dinners, so that the guests might savor the poetry along with the food.

There is food poetry in the Bible, as well. Throughout the Song of Solomon, the male and female narrators compare one another to fruits and other foods. The man's cheeks are compared to a "bed of spices"; the woman's breasts are described as "clusters of grapes" and her nose

Title page of *L'épicurien français*, a popular collection of poems and stories with food themes from early-nineteenth-century Paris. ROUGHWOOD COLLECTION.

as smelling like apples. Figs, grapes, vines, and pomegranates are used to describe their love for each other. The apple tree, standing out among other trees, represents the beloved's standing out among men. Other foods mentioned in the exchange include honey, milk, saffron, and cinnamon.

Food is inherent to many traditional songs and poems of the Celtic world and in England. For instance, an Irish saying goes: "Rye bread will do you good, / Barley bread will do you no harm, / Wheat bread will sweeten your blood, / Oat bread will strengthen your arm." Early Celtic poems tell of affection for such foods as mushrooms, milk, and colcannon, the Irish dish of mashed potatoes with cabbage or kale. In England, a song once accompanied the churning of butter: "Come, butter,

come, / Come, butter, come, / Peter stands at the gate / Waiting for a buttered cake, / Come, butter, come."

In the sonnets, Shakespeare invokes appetite and eating as metaphors for human behavior, beginning with images of famine and gluttony in Sonnet 1, "From fairest creatures we desire increase." In Sonnets 56 ("Sweet love, renew thy force") and 110 ("Alas! 'tis true, I have gone here and there"), appetite represents desire. In Sonnet 75, which opens with "So are you to my thoughts as food to life," appreciation of the beloved is compared to feasting, and the speaker without the beloved is "starved for a look." In Sonnet 52, infrequency of "feasts" gives them meaning, and in Sonnet 118, the eating of "eager compounds" and "bitter sauces" is contrasted with the sweetness of the beloved.

Jonathan Swift, whose concern with matters of hunger reached its most famous height with "A Modest Proposal," the essay in which he ironically suggests fighting hunger by eating children, saw fit to write poetry about onions, oysters, and fishmongers. Robert Burns's "Address to a Haggis" is traditionally recited with the serving of the Scottish dish. The English writer Sydney Smith composed recipes in verse, giving instructions for preparing salad dressing and roasting mutton, for instance.

In the twelfth-century Celtic poem "The Vision of Mac Conglinne," Mac Conglinne helps a king overcome his gluttony. The poem, delectable not only to poetry lovers but also to scholars of medieval Ireland, catalogues an outrageous abundance of foods, including salmon, kale, hazelnuts, sausages, bread, cheese, bacon, and especially milk, which is described as being so thick that it must be chewed.

Food in poetry sometimes carries moral significance. In an archetypal episode in Ovid's *Metamorphoses*, the poor couple Baucis and Philemon share their meager food supply with beggars, who turn out to be gods in disguise and reward the couple with abundance. The biblical story of Eve's eating of the forbidden fruit, said to be an apple but possibly a pomegranate, is portrayed as the first human sin and the reason for man's state of sin. The story of Eve's giving in to the tempting fruit also starts off John Milton's epic on the fall of mankind, *Paradise Lost*. In Chaucer's *Canterbury Tales*, food is an important element in maintaining the balance of bodily humors, and gluttony is addressed as one of the Seven Deadly Sins. Gluttony is severely punished in Dante's hell. And food taboos are part of the human struggle: In Byron's *Don Juan*, a starving crew of seamen resort to cannibalism, but only after a long and horrible effort to avoid it.

Food in poetry can have transformative, and sometimes destructive, powers. In the English epic *Beowulf*, feasting (which always involves plenty of drinking) is generally followed by sleep, which makes the men vulnerable to attacks by the monster Grendel, who feasts on men. (Feasts in *Beowulf* are also given to honor people, and are the backdrop against which many discussions and con-

frontations take place.) In Samuel Taylor Coleridge's "Kubla Khan," the consumption of milk and honey is linked to an altered state of mind. John Keats paid close attention to food in his poems and letters; in his poem "La Belle Dame Sans Merci," the beautiful woman destroys a knight by feeding and seducing him. The food, like the sexual attraction, is central to his undoing.

Some poets invoke food to convey matters of the spirit. T. S. Eliot's question "Do I dare to eat a peach?" conveys the jaded frame of mind of the speaker of "The Love Song of J. Alfred Prufrock." Emily Dickinson uses hunger metaphorically; in the poem "Hunger," hunger and dining express loneliness and love. Another poem, "Forbidden Fruit," makes a pithy statement about human nature: "Forbidden fruit a flavor has / That lawful orchards mocks; How luscious lies the pea within / The pod that Duty locks!"

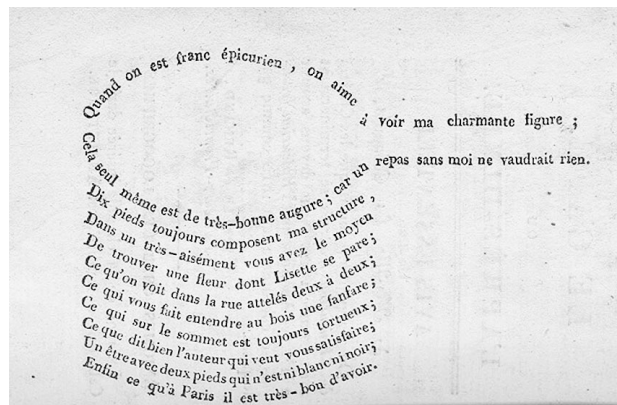

Some poets simply delight in the discussing of food. Pablo Neruda, in his *Elemental Odes*, writes about artichokes, lemons, and olive oil (and the use of the oil in mayonnaise and salad dressing). Ogden Nash has a book of light verse about food. D. H. Lawrence wrote poems entitled "Pomegranate," "Peach," "Medlars and Sorb-Apples," "Figs," and "Grapes." A. E. Housman celebrates the cherry tree in "Loveliest of Trees, the Cherry Now." William Carlos Williams's famous "This Is Just to Say" has immortalized some irresistible plums in an icebox; the savoring of plums occurs also in his "To a Poor Old Woman." The contemporary American poet Robert Hass weaves lush California cuisine into many poems.

Poetry and food may be coming back together, as they were in ancient times. Enough contemporary poets have written poems about food to fill a number of anthologies of food poems, including one devoted exclusively to poems about potatoes (*Spud Songs*, ed. Gloria Vando and Robert Stewart).

**ARTHROPODS: INSECTS, ARACHNIDS, AND CRUSTACEANS.** Arthropods are animals with exoskeletons (external skeletons), segmented bodies, and jointed legs. They are the largest group of animals on Earth and include insects, crustaceans, and arachnids. Insects include organisms such as beetles, grasshoppers, and butterflies. They are mostly terrestrial, small in size, and typically herbivorous. Many species of insects are used as food, and they are traditional food sources in many areas of the tropics. Crustaceans include lobsters, crabs, crayfish, and shrimp. They are mostly aquatic animals, and some, like lobsters and crabs, are relatively large animals. (Crustaceans are discussed below, and are covered in further detail in the article "Crustaceans and Shellfish.") Throughout history, the larger crustacean species have been highly prized food sources. Arachnids include spiders and scorpions, some forms of which are used as food.

The arthropod's exoskeleton is a tough cuticle made of chitin that protects the organism and provides anchor points for muscles. The exoskeleton in crustaceans is rich with calcium carbonate and is particularly hard and thick. The exoskeleton limits an organism's ability to grow in size and must be periodically shed (molted) as the

organism grows. Most arthropods go through a series of molts and become more adultlike with each succeeding one.

Some insects, like flies, wasps, beetles, and butterflies, go through larval and pupal stages that are quite different from the adult stages of those species. As embryos, these organisms develop into a larva that is relatively immobile and specializes in eating and storing fat. The larva then transforms into a pupa (an intermediate stage between larva and adult), and finally into an adult that is highly mobile and specializes in reproduction. In insects that undergo such a metamorphosis, the larva is generally the largest form and the one that humans typically prefer as food. The advantage, for humans, of consuming larval insects is that during immature stages of development, insects are soft-bodied and typically high in fat; in addition, the larval stage is often the stage of the life cycle in which individual insects can be found in the greatest aggregations. For example, in the order Lepidoptera (butterflies and moths), insects are in their largest form and have the highest energy (caloric) value during the larval stage of the life cycle. In contrast, the adult forms of Lepidoptera have lower body mass, a hardened exoskeleton, and are more mobile and widely dispersed than larvae.

The crustaceans used as food are aquatic animals that are widespread geographically. Shrimp, lobsters, and crabs inhabit marine ecosystems, and crayfish inhabit freshwater ecosystems. Shrimp are the smallest crustacean and range in size from that of a small insect to over twenty centimeters (seven to eight inches). They tend to live close to the bottom, or in midwater, and feed on plants and small animals. They are food for predatory fish like cod, pollock, and flounder. Lobsters, crabs, and crayfish are larger than shrimp and are important benthic (bottom-dwelling) predators in local ecosystems. The American (*Homarus americanus*) and European (*Homarus gammarus*) species of lobster are found in the northern Atlantic Ocean. Adults feed on plant material, shellfish, sea urchins, and crabs. They are solitary animals that defend territory around their shelter (spaces under rocks or large crevices), and they are most active in foraging at night. Spiny (rock) lobsters are found in warm tropical and temperate seas. They feed on snails and clams and small crustaceans and are prey for sharks, octopus, and finfish. They lack the larger claws of the American and European lobsters and are gregarious animals that sometimes migrate long distances.

Crabs are the rounder bodied (compared to shrimp and lobsters) crustaceans that walk sideways; some even swim. The species of crab used as food vary in size from less than two pounds for the Dungeness crabs (*Cancer magister*) to up to twenty-five pounds for the Alaskan king crab (*Paralithodes camtschaticus*). Adult crabs are omnivores and dominant predators in local food webs. They feed on shellfish, finfish, and other crustaceans, as well as on detritus (debris). Crabs are widely distributed geographically: Species like the gazami crab (*Portunus trit-*

*berculatus*), the swimming crab (*Portunus pelagicus*), and the blue crab (*Callinectes sapidus*) are tropical or subtropical in distribution. The snow or queen crab (*Cheonoecetes opilio*) is found in the cold seas of the North Atlantic and Pacific Oceans and the Sea of Japan. The most spectacular crabs are the king crabs that live off the coast of Alaska. The red king crab (*Paralithodes camtschaticus*) is the largest: males of this species can grow to up to twenty-five pounds and have a leg span of five feet across. The blue and the golden king crabs (*Paralithodes platypus* and *Lithodes aequispinus*) are somewhat smaller than the red king crab, but they are still king-sized.

Crayfish (or crawfish) look somewhat like lobsters, but they inhabit freshwater ecosystems and are primarily temperate in distribution. North America contains the greatest species diversity of crayfish. They feed on aquatic and semiaquatic vegetation, invertebrates, and detritus. North American species range in size from two to three ounces (50 to 80 grams), but much larger species exist in Australia.

### History of Consumption

European populations and European-derived populations in North America historically have placed taboos on entomophagous eating practices (the consumption of insects) and continue to do so. This is notwithstanding the repeated attempts by entomologists to make insects more appealing. One of the best-known attempts is Ronald Taylor's 1975 book *Butterflies in My Stomach*, and the accompanying recipe guide, *Entertaining with Insects* (1976).

Although entomophagous eating practices have ceased in Europe, insects were at one time frequently eaten throughout the continent. Rural inhabitants of Europe consumed Cockchafer grubs until the 1800s, and these grubs were an important source of protein in Ireland during the famine of 1688. The Greeks and Romans also held some insects in high esteem as a food source. Ancient Greeks considered grasshoppers a delicacy, and even Aristotle wrote of eating cicadas. He considered them tastiest just before the final instar (stage between two molts), but females laden with eggs were also considered to be very good. The Greeks and Romans also ate a large Melolonthid grub, possibly *Lucanus cervus*, which Pliny wrote was fattened before consumption.

For many other populations the consumption of insects has continued into the early twenty-first century, or not long before that time. In Mexico a well-known example of cuisine involving insects is *ahauatl*, a mixture of hemiptera eggs, that Francisco Hernandez first described in 1649. The eggs were also dried and used as a condiment in the preparation of a traditional Christmas Eve dish, *revoltijo*. In Colombia the giant queen ants of the genus *Atta* are considered a gastronomical delicacy. There the consumption of giant queen ants can be traced to precolonial times: Gonzalo Jimenez de Quesada, founder of the Colombian capital city Santa Fe de Bo-

gotá, first described their use by local peoples in the highlands in 1555.

The consumption of a wide variety of insects has been reported among Amerindian groups in South American rain forests, and insects have probably been part of that region's diet for a very long time. The insects that appear to be consumed most commonly are ants of the genus *Atta*, palm grubs, and caterpillars of various sorts. The naturalist Alfred Wallace first described the consumption of *Atta* queen ants in 1854:

They are eaten alive; the insect being held by the head as we hold a strawberry by its stalk, and the abdomen being bitten off, the body, wings and legs are thrown down to the floor, where they continue to crawl along apparently unaware of the loss of their posterior extremities.

Palm grubs, the large, fatty, legless larvae of wood-boring weevils (*Rhyncophorus*) found in the pith of felled palm trees, are a highly esteemed food among Amerindians. Bancroft, writing in the eighteenth century, claimed that palm grubs were equally highly esteemed by Europeans in Surinam, particularly by the French.

In Africa the use of insects as food is quite widespread and probably has deep historical roots. The mopane worm (*Gonimbrasia belina*), the so-called snack that crawls, is one of the best known edible caterpillars. Termites are also utilized as food, especially in the early rainy season when the reproductive forms swarm from the nest. At one time, termites were such an important addition to the diet that their mounds were often disputed as property. Locusts (grasshoppers that go into a swarming phase), in particular the desert locust (*Schistocerca gregaria*), also play a large role in the diet of Africans. In African history the locusts were so popular that people actually welcomed the arrival of swarms.

In the Middle East the desert locust was also a major source of food historically. Perhaps the most well-known incident involving locust eating was John the Baptist's ordeal in the desert during which he survived on locusts (St. John's bread) and honey. By using locusts as food he was observing the decree of Moses, "These ye may eat; the locust after his kind and the bald locust after his kind, and the cricket after his kind and the grasshopper after his kind" (Leviticus 9:22).

In Asia the consumption of insects as food was described from the Chung-Qiu dynasty (770–475 B.C.E.) and continues to the present day. The most commonly consumed food insects in that region are bee brood (larvae and pupae), beetles such as *Dytiscid* and *Hydrophilid* beetles, and the giant water beetle (*Lethocerus indicus*), the larvae of weevils like *Rhyncophorus*, and locusts of the genera *Oxya* and *Locusta*. Perhaps the most well-known insect eaten in the region is the pupa of the silkworm *Bombyx mori*.

In Australia the black honey ant (*Camponotus inflatus*) is a highly sought-after food of Aboriginal Australians

Collecting bamboo grubs for food in rural Thailand. © MICHAEL FREEMAN/CORBIS.

and is even considered a totem animal by some clans. It is similar to the honey ant found throughout North and Central America: a modified worker ant with an enlarged body the size of a grape that is full of nectar. Digging up these ants is still considered an important traditional practice and is still taught to children. Witchetty grubs were also an important food of Australian Aborigines. The name witchetty grub refers to any number of root-boring larvae and probably includes Cossid moth larvae (*Xyleutes leucodomochla*), giant ghost moth larvae (*Hepialidae*), and longicorn beetle larvae (*Cerambycidae*). One of the most unique and well-documented examples of entomophagous eating habits in Australia was the annual feast of bugong moths (*Agrotis infusa*), which occurred until the 1890s. These moths migrate from the plains to aestivate (the summer equivalent of hibernation) in the rock crevices of the Bugong Mountains. Aboriginal Australians from many different tribes traditionally gathered to feast on them. Evidence of these feasts has been carbon-dated as early as 1000 C.E.

## Procurement and Capture

The harvesting of insects varies greatly by species because it is tailored to the ecological and behavioral characteristics of different species, as well as the stage of the life cycle sought. Harvesting is typically done for subsistence or to satisfy the demands of a local market.

The harvesting of larval forms like grubs and caterpillars is relatively easy as long as the food source is known. Caterpillars like mopane worms can be picked from their host trees (mopane trees), or for species like the Pandora moth (*Colorado Pandora lindseyi*), gathered as they descend from their host trees to pupate in the soil. The larva of wood-boring weevils like *Rhynchophorus* can be harvested by splitting open the palm trees they inhabit, and the larva of root-boring grubs like witchetty grubs can be harvested from the roots of their host plant.

Harvesting mobile adults is more of a challenge. One strategy is to harvest at a point of high aggregation. The giant queen ants of the genus *Atta* can be collected as they swarm from the nest on nuptial flights early in the rainy season. Some termites, like *Macrotermes*, can be harvested in the same way. The bogong moths are smoked out of the rock crevices where they gather to aestivate. Social insects that live in large colonies, like ants and termites, can be dug out or lured out by intruding smoke or by inserting a probe, which the soldiers defending the colony will attack. At least one arachnid, the tarantula, can also be attracted out of its burrow using a probe.

Another strategy is to create an aggregation. For grasshoppers and crickets this is done by surrounding them by hunters carrying sticks and driving them into holes or trenches. They can also be captured by dragging bags or nets along the ground and collecting them. A third strategy is to attract the insects to a flame or a light. One species of giant queen ants, as well as some termites and dragonflies, can be attracted to a flame that conveniently singes their wings and makes them very easy to collect. At least one species of beetle can be attracted to a black light.

## Preparation and Consumption

In areas where insects are a traditional part of the diet, they are typically consumed raw or are prepared like other foods, especially other animal food. For example, in Japan grasshoppers, silkworm pupae, and bee pupae are cooked in soy sauce and sugar and served as appetizers. In other parts of Asia, larvae of various sorts, beetles, scorpions, and tarantulas are served fried or stir-fried with vegetables and typical seasonings. In Africa, mopani worms are eaten raw, fried, or cooked in a typical stew after they have been squeezed to remove gut contents.

In general, soft-bodied forms like larvae and pupae are typically fried, grilled, or stewed with local vegetables and seasonings. Larger, hard-bodied forms (such as adults with exoskeletons) like grasshoppers and locusts are typically soaked or cooked in salted water and then

sun-dried, or even grilled like shrimp. The legs and wings are typically removed before they are consumed. The exoskeleton of these organisms is retained and provides a certain crunchiness. Smaller organisms with exoskeletons, like ants and termites, are often roasted or fried. In the past, Native North Americans roasted both grasshoppers and crickets and pounded them together with seeds and berries to make a cake called a “desert fruitcake,” which could be sun-dried and stored.

## Relations to Human Biology

Arthropods are animals and are therefore generally comparable to other animal foods in terms of their nutritional composition. Insects have protein content similar to that of meats like beef and pork. The quality of the protein, however, appears to vary greatly among species; in most cases it is better in terms of amino acid composition than that of plant foods like grains and legumes. The larval stages of arthropods like palm grubs and witchetty grubs are quite high in fat and are similar in that regard to U.S.-style hot dogs. Caterpillars tend to be more muscular and, hence, higher in protein. In terms of micronutrients, insects generally have reasonable quantities of iron, calcium, and B vitamins. As mentioned earlier, the crunchy exoskeleton of insects like grasshoppers is partially composed of chitin, a substance not digested by humans. Little is known about the potential toxic or anti-nutritional factors of insects, although in areas where pesticides are used, toxicity may be of serious concern for all species.

## Contemporary Issues

There is a worldwide general trend towards the reduction of entomophagous eating practices. This may be due to the increased use of pesticides to control insects in agricultural zones or the trend toward the adoption of westernized diets (in other words, diets like those of North Americans and Europeans) in which insects have extremely low status as food or are taboo. Despite the general reduction in the consumption of insects as food, there have been efforts to commercialize some food insects. Entrepreneurs in Australia have introduced some local delicacies like black honey ants, witchetty grubs, bardi grubs (the larvae of a Cerambycid beetle), and Trigona bees to the commercial food market, and some Australian restaurants include insects on their menus. Entrepreneurs in South Africa market mopani worms, and the appearance of caterpillars as ingredients has been a general trend on menus in Africa. Some Asian countries also export food insects as specialty items: Thailand exports frozen steamed ant larvae and pupae, Korea exports pupa of the silkworm *Bombyx mori*, and Japan exports bee pupae in soy to the United States.

There has also been research and development into the rearing of insects as “mini-livestock” in order to meet the subsistence needs, especially the protein needs, of impoverished rural populations. The idea of purposefully raising insects for food is not as far-fetched as it might

seem: for example, many societies have been raising bees for a long time.

**ARTIFICIAL FOODS.** The term "artificial" refers to something produced to imitate nature. Some artificial foods created with rubber or similar materials are incredibly lifelike. People have even placed them on a table when they are away to fool robbers into believing someone is home and ready to eat. These food models are more commonly used in educational settings to help people understand reasonable portion sizes. They are also used in displays, such as restaurant windows, as food spoilage is not an issue. A computer search using the term "artificial food" will locate retail vendors of these food models.

#### Edible Food

The term "artificial food" also creates images of edible food made from substances that do not occur naturally. No wholly artificial foods exist in the strict sense, but

TANG®

Tang®, a powdered orange drink meant to mimic orange juice, was introduced in 1957 and went into national distribution in 1959. It rose in popularity in 1965, when it became part of the diets of the astronauts in the space program. Tang® has been on every manned space flight since *Gemini 4*, including Apollo flights, *Sky Lab*, and the space shuttles. The National Aeronautics and Space Administration (NASA) chose it because of its compact nature as a powder, its convenience, its storage qualities, and its required nutrients, such as vitamins A and C.

Tang® obviously appealed to kids who wanted what astronauts were eating, and hundreds of other powdered beverages followed. Sugar-free Tang became available in March 1985, driven by consumer demand for sugar-free low-calorie beverages.

The popularity of the powdered orange juice substitute gradually dwindled as the convenience of fresh orange juice at a reasonable price rose. For a brief time in the 1990s the popularity of Tang® increased with "Generation X" due to a "Tang and Toast" advertising campaign. Tang® is popular when a convenient dried food is required, such as on camping trips and in the military. It is usually carried by suppliers of dried and dehydrated foods for long-term food storage or specialty grocery stores with a nostalgic supply. The original purpose of Tang® as a convenient, inexpensive powdered drink has been forgotten. After 1999 it was available in pouches, ready to drink, in flavors such as Fruit Frenzy and Orange Uproar.

Rumors abound that some consumers have used Tang® Drink Mix to clean their dishwashers. Tang® does contain citric acid, which can act as cleaning agent. Kraft Foods has taken the position that Tang® Drink Mix is intended to be a food product, and the company does not advocate its use for any other purpose.

some foods are called artificial or seem artificial to some people. Viewing a food as artificial is most likely if it contains ingredients, such as colorings or flavorings, that are not inherent in the food. An example is artificial strawberry flavoring created in the laboratory to mimic the natural taste of fresh strawberries.

Foods may also be "artificial" for medical reasons or to suit personal beliefs. For example, artificial milk is created for infants born with a genetic disease called phenylketonuria (PKU). The artificial milk replicates the

Artificial foods are popular in Japan, where they are widely used in restaurant window displays to help customers make decisions. The food is often so realistically made that it cannot be differentiated from the actual product it is imitating. Shown here is an elaborate window display in the Shinjuku District of Tokyo. © MICHAEL S. YAMASHITA/CORBIS.

nutritional content of real milk but lacks a specific amino acid, phenylalanine, not tolerated by an infant with PKU. Without this artificial milk, infants with PKU would develop severe mental retardation.

Vegetarian food substitutes, such as imitation bologna, may be viewed as “artificial” by some because they imitate nature. They may look and taste similar to a meat product, yet they contain no meat. Others argue that the term “artificial food” may not apply here, as many vegetarian meat substitutes contain only all-natural ingredients. Most would conclude that the consumer definition of artificial food relates more to the presence of any artificial ingredient, such as nutrients, artificial coloring, or artificial flavoring, that possesses ingredients or attributes that simulate another food.

Sometimes artificial ingredients are added to provide a nutrient that would be in the food in its natural state. For example, orange juice has vitamin C, so Tang® Drink Mix is fortified to contain at least 100 percent of the daily value for vitamin C (see sidebar on Tang®). Sometimes ingredients are added but not to the same level the natural product would contain. For example, potassium is added to Tang®, primarily in the form of potassium citrate. A small amount of potassium is contributed by orange juice solids and other ingredients. The body uses the potassium in Tang® from potassium citrate just as it would use the naturally occurring potassium in foods and beverages. The quantity, though, is different from that of natural orange juice. The potassium content of Tang®

Drink Mix is 50 milligrams per 8 fluid ounces. Orange juice contains approximately 470 milligrams per 8 fluid ounces.

### Foods Containing Artificial Flavor or Color

The consumer looks for the term “artificial” on food labels to distinguish between foods that are in their natural states and those that have been modified in some way. On the label the term “artificial” is applied to flavor or color as defined by the federal government. For example, this is the federal definition of artificial flavor:

The term artificial flavor or artificial flavoring means any substance, the function of which is to impart flavor, which is not derived from a spice, fruit or fruit juice, vegetable or vegetable juice, edible yeast, herb, bark, bud, root, leaf or similar plant material, meat, fish, poultry, eggs, dairy products, or fermentation products thereof. Artificial flavor includes the substances listed in Secs. 172.515(b) and 182.60 of this chapter except where these are derived from natural sources (*Code of Federal Regulations*, Title 21, vol. 2, 2001, pp. 73–78).

In simpler terms, for the purposes of nutrition labeling, artificial flavor means anything added to food for flavor that is not taken directly from whole foods.

The federal definition of artificial color or artificial coloring means any “color additive” as defined in Sec. 70.3(f) of the food code. Some food colors obtained largely from mineral, plant, or animal sources may be listed on the label with the general term “artificial color.” Regulations require certification of colors derived primarily from petroleum, known as coal-tar dyes. Some color additives must be listed by name on the label. These are additives that are safe for most people but have been identified as a problem for a small number of consumers. For example, FD&C Yellow No. 5, listed as tartrazine on medicine labels, must be individually labeled because it causes hives and itching in a small proportion of consumers.

Though reactions to color additives are rare, the Food and Drug Administration (FDA) wants to know about them. The agency operates the Adverse Reaction Monitoring System (ARMS) to collect and act on complaints concerning all food ingredients, including color additives. Consumers can register complaints by contacting the FDA district offices in their local phone directories or by sending written reports to the ARMS at the Food and Drug Administration in Washington, D.C.

### Determining if Food Has Artificial Flavor or Color

Artificial ingredients in the food supply are generally considered safe for individuals without specialized medical conditions such as specific food allergies. Some consumers prefer to avoid foods deemed artificial anyway, as a precaution that fits with their own beliefs. Thus nutrition labeling assists these consumers in following their personal preferences.

Grocery stores usually have mechanisms that allow consumers to decide if they want to purchase the food. For example, if a strawberry shortcake contains flavoring from strawberries enhanced by artificial flavor, the box will be labeled “natural and artificial strawberry flavor.” If the food contains solely artificial flavors, it will be labeled “artificial strawberry flavor.”

Foods packaged in bulk containers for retail stores may not contain a nutrition label. The labeling information for the food, however, should be displayed plainly in view or on a counter sign. Restaurant food is more challenging, as restaurants are not required to provide nutrition labeling.

**ASIA.** See **Asia, Central; China; India; Japan; Korea; Southeast Asia.**

**ASIA, CENTRAL.** The mention of Central Asian foodways usually conjures up competing images of nomadic and sedentary lifestyles. In one, the roving sheepherder astride a brawny steed, between base camp and mountain pasture, clutches a leather pouch of fermented milk. The other vision includes the long-beard in his colorful robe and headdress, enjoying perfumed pilaf in a tranquil teahouse. While scholars quibble over cultural and physical boundaries of Central Asia, culinary cultures of the region represent an intriguing mix of steppe and settlement, highlands and lowlands, Turkic and Iranian.

### **Culinary Culture and Geographic Setting**

Generally speaking, hospitality is the defining feature of this underpublicized cuisine. For all the ethnic and geographic variations in Central Asia, the food of the region exhibits more homogeneity than disparity. Basic methods of preparation, main ingredients, common dishes, and predominant cultural traditions of Islam all reflect the enriching exchange along the heart of the storied Silk Road. The regional larder consists of mutton, rice, cumin, coriander, cilantro, dill, nuts, tea, dried fruits, and yogurt, distinguishing it from Chinese and European fare. Meal preparation is often conducted outside over fire, with cast-iron cauldrons (*kazan*) for frying, simmering, and steaming; open-flame braziers for grilling; and *tandir* ovens for roasting meats and baking breads. Customary dishes throughout the region include soups and stews, pilafs, noodles, steamed dumplings, grilled meats on skewers, flatbread, savory pastries, and halvah.

The geographical limits of Central Asia, once called Turkistan, include the Soviet successor states (Uzbekistan, Turkmenistan, Tajikistan, Kazakhstan, and Kyrgyzstan), and Xinjiang in northwest China. Others do not

hesitate to add other Turkic-language areas, like the Caucasus, Turkey, and parts of Siberia, while some embrace Mongolia, Iran, Afghanistan, northern India, Pakistan, and even Tibet in the Central Asian cultural orbit.

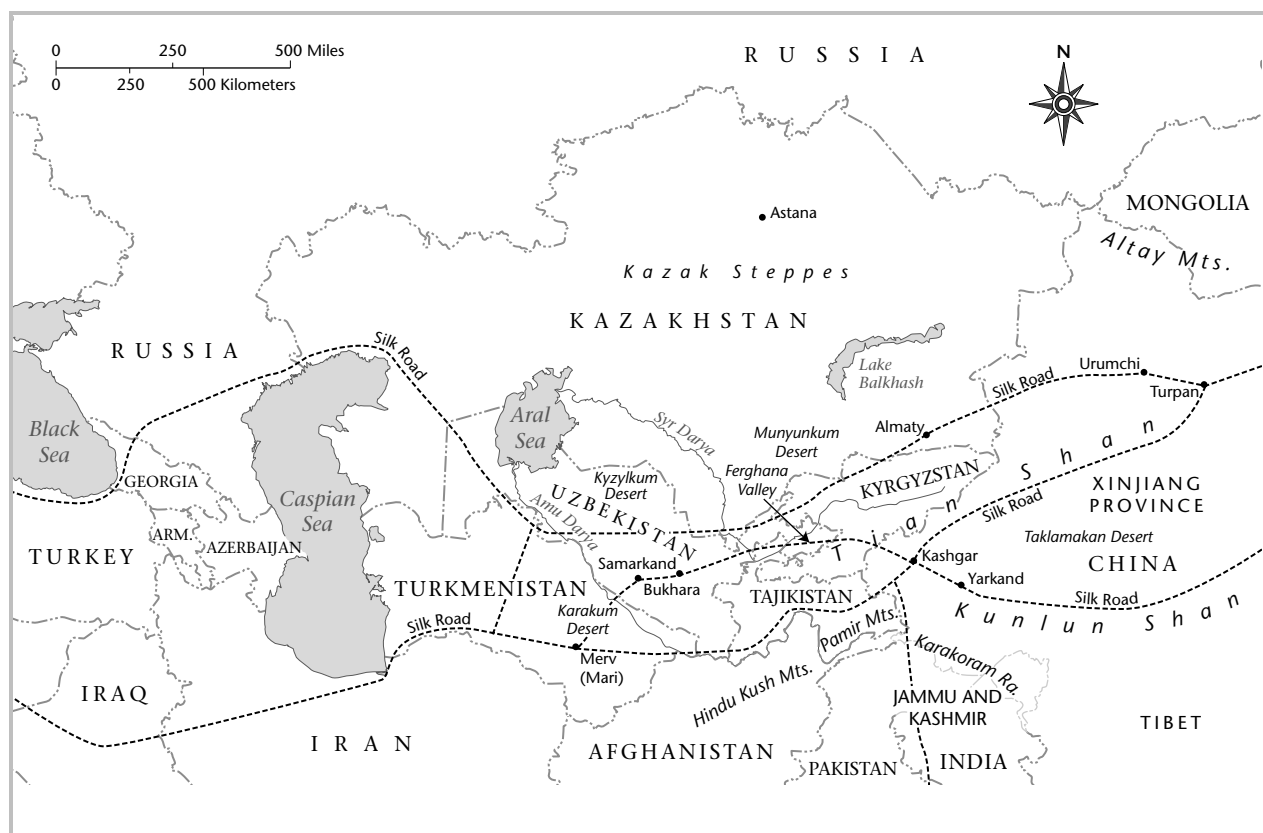

The thriving culture of Iran was the primary influence on Central Asian society, with later Arabic and Mongol contributions. One hundred and fifty years of Russian power and fifty years of intensive Chinese subjugation of the region have considerably altered the foodways. Well-documented Soviet problems of collectivization and distribution homogenized local diets. The turbulent history of Xinjiang continues, with Chinese migrants and laborers, particularly from Sichuan, flooding the region after the 1960s, dropping the Turkic Uighur population from roughly 75 percent to less than 50 percent. In China proper, Uighur cuisine is segregated and disparagingly referred to as Muslim food.

### **Diet and Foodstuffs**

Greek humoral theory, as propagated by ibn Sina of the eleventh century, still affects the diet of millions in the region. Combined with traditional Chinese thought, Central Asians consider food to have either “hot” or “cold” (Farsi, *sardi* or *garmi*) qualities, serving both medicinal and nutritive functions. Three meals a day are standard, each including tea and flatbread (*nan* or *naan*). The largest meal is usually taken in the evening.

The spirited bazaars of Central Asia—part marketplace, part carnival, and part town square—capture the Silk Road mystique. Aromatic spices take center stage, though only cumin, red and black pepper, and coriander seeds are used in abundance. Herbs of distinction include cilantro, dill, parsley, and celeriac leaves. Seasoning is generally mild, but sauces, relishes, and even whole peppers are added for punch. Other flavor enhancers are white grape vinegar and fermented milk products. Rendered sheep fat is the general cooking oil, though vegetable oil and cottonseed oil are widely used. Olive oil and butter are not traditional cooking fats.

The Asian sun sweetens market produce. Delicious tomatoes, peppers, onions, cucumbers, and eggplants comprise the basic vegetables. The area also offers unique varieties of pungent green radishes (*turup*), yellow carrots (actually turnips), and a prodigious selection of pumpkin and squash. Dolma, meaning “stuffed” in Turkish, may be created from any vegetable—cabbage, grape leaves, peppers, tomatoes, and so forth—by hollowing it out or wrapping it around a filling. Spring fruits traditionally include grapes, apricots, strawberries, cherries, figs, and peaches. The tree harvest in autumn brings apples, quinces, persimmons, and pears. Winter delivers lemons, mandarins, pomegranates, and smooth-skinned melons. Melon slices are also sun-dried and braided into long ropes to take their place alongside dried apricots, figs, dates, and raisins.

## Core Cuisine

**Meat and rice.** Lamb and mutton, mainly fatty-tailed sheep, are the favorite protein of Central Asians. The fat, which imparts a sweet and rich quality to a dish, is valued more than the meat itself. Beef and chicken are consumed in substantial quantities, and horse, camel, and goat are not uncommon. Fish, though not eschewed, is rarely available, and Islamic dietary law forbids pork. *Shashlyk* (shish kebab), the standard street food, is prepared with beef, mutton, or minced meat and served with flatbread and lightly pickled onions. A kebab of fresh sheep liver and tail fat is a true luxury. While Westerners forget their charcuterie traditions, no part of an animal in Central Asia is ever wasted. There are still dishes made of lungs, intestines, and sheep's head and trotters.

Pilaf (*palov*) epitomizes Central Asian cuisine. A ceremonial dish for guests and family days, pilaf is so ubiquitous that there is sometimes a mistaken impression that it is their only dish. Meat, onions, and carrots are sautéed, then simmered to a broth, and covered with rice. Raisins, barberries, chickpeas, or dried fruit may be added for variety. Cumin is often the sole spice, while turmeric is added on special occasions for its golden color. Similar to an American barbecue, pilaf preparation is considered

a manly challenge. Working with only a woklike *kazan* and spatula (*kapkir*), an *oshpaz*, master pilaf chef, can serve up to a thousand people from a single cauldron, making him much in demand for festivals and weddings.

**Bread and noodles.** Flatbread is baked daily at home or in communal ovens. Bread is considered holy and accompanies each meal. Most baked goods are made with wheat flour, though mung bean and corn flour are used also. Some flatbreads are topped with onions, pieces of sheep's fat, or even meat. Others are glazed with *kalonji*, anise, poppy, or sesame seeds. In Xinjiang the round plump breads astoundingly resemble New York City bagels. *Katlama*, related to the Indian *paratha*, is flaky unleavened bread cooked on a skillet.

The steppe nomads have added flour and dough to their soups for centuries. A dish of square flat noodles topped with boiled meat is called *beshbarmak* in Kazak-Kyrgyz areas. From farther east come steamed dumplings, *manty* (Korean *mandoo*), vying with pilaf for the national dish in Kyrgyzstan, Kazakhstan, Uzbekistan, and Chinese Turkistan. Uighurs have mastered hand-pulled noodles, common in Korea and China proper. Made with only soft wheat, water, and salt, the transformation of a ball of dough into noodle threads in a mat-

## PROVERBIAL LAND OF MILK AND HONEY

Although God did not mention Central Asia when promising Moses a “good and spacious land, a land flowing with milk and honey,” the region certainly fits the description. The Eurasian herders, having domesticated sheep and goats roughly ten thousand years ago, realized that milk, in addition to the meat and wool of their flocks, was essential to their survival. The pastoralists took advantage of microbiology to improve the flavor of fresh milk, make it more digestible and nutritious, and increase its shelf life. The resulting dairy product is determined by controlling the action of bacteria, enzyme, or yeast. Milk, either fresh or skimmed of cream, may be of several sources—ewe, goat, cow, camel, mare, and dri (yak). The first step is simply separating fresh cream from the milk to make a soured clotted cream, or *kaimak*, enjoyed with flatbread and honey. The honey is imbued with a marvelous flavor due to the nectar gathered from cotton and grape blossoms and the varied mountain valley flowers, grasses, and trees.

Fresh milk quickly sours through fermentation in warm conditions, essentially the same bacterial process employed for pickles, olives, or sourdough bread. Yogurt (*katyk*) is used in soups, beverages, and even doughs to add a pleasant sourness, with the lactic acid produced by bacteria breaking down the milk sugar. With reduced lactose, the cultured products become more digestible

for most Central Asians, who, along with 70 percent of the world, have a dairy intolerance. Fermented camel milk is *shubat*, and *agaran* is its cream. Mixing *katyk* and water creates a refreshing salty drink, *ayran* or *chalop* (Kyr), similar to the Indian *lassi*. Drained yogurt results in *suzma*, a fresh curd cheese eaten plain, in salads, or with soups and main courses as a garnish. Adding a rennet enzyme to milk makes *panir* or soft cheese, unaged, white, and rindless.

*Kumys*, fermented camel's or mare's milk, made famous by numerous Western travelers, including Marco Polo, has been subjected to both bacterial and yeast fermentation. Caucasian kefir is made with a similar process. *Kumys* or *ayrag* (Mongolian), primarily made with mare's milk, is the mildly alcoholic drink (up to 4 or 5 percent) of the nomads and may also be slightly fizzy with carbonic acid. *Saba* is a Kazak leather sack for making *kumys* that imparts a smoky, earthy quality. Refusing an offer of *kumys* may cause offense. Mare's milk has four times more vitamin C than cow's milk, aiding a pastoral diet scarce in fruits and vegetables. The remaining milk or whey from *kumys* or *suzma* is salted and sun-dried, formed into balls or bricks, and called *qurut* or *qurt*. This form, which is eaten often as a snack, lasts the winter months and may be added to soups or reconstituted as a drink.

ter of minutes is both compelling performance art and a dying culinary method.

A casing of dough with a typical filling of fatty mutton and onions becomes a number of other dishes simply by varying the cooking technique. If the dough is fried, the dish is called *belyashi* (Kazan Tartar) or *chebureki* (Crimean Tartar). The Turkish *borek*, also a fried savory pastry, may be related to the Slavic *pirog*, *piroshki*, and *pierogi*. Baked in a *tandir*, the dish is called *samsa* (Uzbek) or *sambusa* (Tajik), like Indian *samosa*. Steamed *manty* or *hoshan* (Kazak) are usually topped with a sauce of tomatoes, potatoes, and diced mutton. Smaller boiled versions of *manty* are *chuchvara*, *pelmeni* (Siberian), *tushbera* (Tajik), and *joshpara* (Farsi).

### Hospitality and Traditions

**Meals and customs.** Central Asian cookery often requires great sacrifices on the part of the host. The Uzbek adage “*Mehmon otanda ulugh*” (the guest is greater than the father) remains accurate for most of the Muslim East. Generally, guests remove their shoes before entering the

house and are seated at a low table (*takhta*) or on the floor with a *kurpacha*, or cushion. Diners gather around a *das-tarkhan* (literally, tablecloth), which is an enormous assortment of food offered to the honored guest. On some occasions, men and women are separated. Special meals are eaten commensally by hand and can last for several hours with multiple courses and endless cups (*piala*) of tea. Though most of the region embraces Islam, alcohol is widely accepted in the successor states.

In addition to the ever-present pilaf, some distinct dishes are served during Islamic holidays. Navrus, the Muslim New Year, corresponds to the spring equinox. *Halim*, wheat porridge, is prepared from boiled meat and wheat grains, seasoned with black pepper and cinnamon. A children's favorite, *nishalda*, popular during Ramadan, is made with whipped egg whites, sugar, and licorice flavoring. *Sumalak*, symbolic of friendship and tolerance, is among the most traditional dishes. Prepared only by women, overnight, wheat sprouts are blended with oil, flour, and sugar and cooked on low heat. Eid-ul-Fitr marks the end of Ramadan with three days of feasting.

**Tea and dessert.** Freshly made green tea, the drink of hospitality, complements every meal. Teatime, which may occur at the slightest cause, often includes flatbread, sweets, fruits, and pastries. Dried fruit with nuts—walnuts, pistachios, and almonds—is also a perfect accompaniment. Black tea is common in the Russian regions. Both teas are served with sugar, milk, salt, butter, or even fruit preserves. Uzbeks have a custom called *shapirish*, whereby the hostess returns the first two cups back into the teapot to stir the infusion. Thus the tea is described as going from mud (*loy*) to tea (*choy*) to wine (*moy*).

As sugar cane originated in India, sweets are a gift from the south, via Iran. This tradition produces tea sweets such *chakchak*, fried dough with honey; *urama*, fried spiraled strips of dough with powdered sugar; sugar-coated almonds; and *novvot*, crystallized sugar. More familiar halvah and *paklava* are also common desserts. *Sharbat* is fruit juice that migrated to Europe as frozen sherbet.

Food available outside the home includes street food and that from cafés, modern restaurants, and the traditional *chai-khana* (tearoom). Ideally near a poplar-lined stream or in a cool courtyard orchard, it is a gathering place for fraternity and socializing. The *chai-khana* in many ways functions like a community center and helps

preserve certain aspects of Central Asian identity obscured by colonial powers.

### Regional Variations and Specialties

The cuisines of Central Asia may be divided into three overlapping groups: Tajiks, Turks, and nomadic Turko-Mongol tribes. However simplistic, this categorization provides a more coherent approach to understanding the culinary cultures of Central Asia than organization along the arbitrary national boundaries. Numerous subcuisines from other ethnic minorities, such as Koreans, Tartars, Dungans (Chinese Muslims), Slavs, and Germans add to the culinary diversity of the area.

**Sedentary cuisine.** The Iranian-Tajik influence extends from Tajikistan and southern Uzbekistan to Iran and Afghanistan and beyond to northern Pakistan and Jammu-Kashmir in India. These cuisines employ more vegetables and legumes, resort to complex seasonings, and boast elaborate sweets. Years of civil strife in Tajikistan and Afghanistan have devastated food supplies and interrupted traditional foodways. Generally, the farther away from the nomadic steppe, the more complex the spice blends and seasoning of the dishes. In Tajikistan and Uzbekistan, an unusual dish is *tubum barak*, an egg-filled ravioli flavored with sesame-seed oil. Tamerlane

and his entourage of craftspeople from Samarkand, cooks included, brought the meat-eating tradition to India along with many fruits, particularly the melon and grape. The descendants of these cooks—the Wazas—are the master chefs of Kashmir.

The Turkic group of languages claims roughly 125 million speakers and stretches from Siberia to the Balkans. Uzbeks and Uighurs, as settled Turks, favor pilafs, noodles, and stews. Since the oasis civilization is a middle ground, literally and figuratively, between the Iranian courtly cuisine and the pastoral nomads, their food has become most representative of Central Asian cuisine. In Uzbekistan, *moshkichiri* and *moshburda* are common meat and mung bean gruels. *Dimlama* is braised meat and vegetables cooked in a pot sealed with dough. Its origins may be tied to *dumpukht* in Farsi, signifying food cooked in its own steam, shortened also in India to *dum*, as in *dum-aloo*. Apricot seeds are specially treated and roasted in ash to produce an exceptional snack. Because of linguistic ties, Azerbaijan and Turkey are often included in Central Asian culinary culture, as these countries share roots, not to mention cooking methods and many dishes, with the Eurasian nomads.

**Nomadic cuisine.** Of all the Central Asian peoples, none has experienced such dramatic cultural upheaval due to colonization, industrialization, and urbanization as have the nomads. The traditional meal of steppe and highlands was meat on occasion, milk products, and the stray onion. As Turkmenistan is mostly desert, vegetable and grain cultivation is challenging. *Chorek* (flatbread), gruel, and tea remain typical for most meals.

In Soviet times the Turkmen, Kazaks, and Kyrgyz were forcefully settled into dreary apartment blocks. Separated from the land and their herds, the nomads adopted many Russian or Uzbek foods and customs. Kazaks and Kyrgyz claim as national dishes *beshbarmak* and *kumys*, fermented mare's milk. Horsemeat sausage (*kazy*), when served with cold noodles, is called *naryn*. Barley, wheat, and millet are quite common; from them comes *dzarma*, fermented barley flour. *Boso*, or fermented millet, and *boorsak*, a ritual dish made from small pieces of deep-fried dough, are also found in Tibet by the same name. When the Uighurs and Dungans fled China in the late nineteenth century, they brought *laghman*, other noodle dishes, and spicy peppers that were quickly embraced by the Kazaks and Kyrgyz.

The diminished state of traditional foodways in Central Asia is often decried, particularly when judging the cuisine through the distorting prism of Western restaurant culture. These Eurasian civilizations were completely transformed during the colonial experience. However, the trend of globalization triggers entrenchment of cultural heritage and local foodways. As borders open, outside interest is countered with a pronounced revival and demonstration of ethnic identity. If domestic traditions and hospitality persevere, the Central Asian culinary arts and its foodways are bound to flourish.

#### ASSESSMENT OF NUTRITIONAL STATUS.

Nutritional status is the balance between the intake of nutrients by an organism and the expenditure of these in the processes of growth, reproduction, and health maintenance. Because this process is highly complex and quite individualized, nutritional status assessment can be directed at a wide variety of aspects of nutriture. These range from nutrient levels in the body, to the products of their metabolism, and to the functional processes they regulate. Nutritional status can be measured for individuals as well as for populations. Accurate measurement of individual nutritional status is required in clinical practice. Population measures are more important in research. They can be used to describe nutritional status of the group, to identify populations or population segments at risk for nutrition-related health consequences, and to evaluate interventions.

The choice of nutritional status assessment method must be made mindful of the level at which one wants information, as well as of the validity and reliability of the method. All methods have error. All methods produce imperfect measures that are indirect approximations of the process. Whatever method is chosen for assessment of nutritional status, the data obtained must be compared with reference data to produce an indicator of nutritional status. The quality of the available reference data is, therefore, another factor that affects the assessment data.

Ideal methods are sensitive and specific. Unfortunately, it is difficult to achieve both in the assessment of nutritional status. Sensitivity refers to the ability of a technique to correctly identify those affected by a condition (for example, undernutrition) as having that condition. Specificity refers to the ability of a technique to correctly classify normal individuals as having normal nutritional status. Body mass index ( $\text{wt}/[\text{ht}]^2$ ) is a global measure of nutritional status that illustrates the difference between these two constructs. Most persons who consume insufficient energy have low body mass index, so the measure is sensitive. However, there are other causes of low body mass index, including genetics and disease, so body mass index is not specific to nutritional status.

The assessment of nutritional status is commonly summarized by the mnemonic “ABCD,” which stands for anthropometric measurement, biochemical or laboratory tests, clinical indicators, and dietary assessment. This review will focus on anthropometric and dietary techniques.

### **Anthropometric Approaches to Nutritional Status Assessment**

Anthropometric approaches are, for the most part, relatively noninvasive methods that assess the size or body composition of an individual. For adults, body weight and height are used to evaluate overall nutritional status and to classify individuals as at healthy or nonhealthy weights. In the United States of America and other industrialized countries, the emphasis for unhealthy weight is overweight and obesity. The standards for these have changed over time. The most recent classification is to use body mass index (BMI, in  $\text{kg}/\text{m}^2$ ) (Kuczmarski and Flegal, 2000). BMI, regardless of age or population, is normal at 18.5 to 25.0  $\text{kg}/\text{m}^2$ , overweight at 25.0 to 29.9  $\text{kg}/\text{m}^2$ , and obese at over 30.0  $\text{kg}/\text{m}^2$  (USDA & USDHHS, 2000). In general BMI greater than 30 is assumed to be due to excessive adiposity.

In children, growth charts have been developed to allow researchers and clinicians to assess weight- and height-for-age, as well as weight-for-height. For children, low height-for-age is considered stunting, while low weight-for-height indicates wasting. In addition to weight and height, measures of mid-arm circumference and skinfold measured over the triceps muscle at the mid-arm are used to estimate fat and muscle mass. Anthropometric measures of nutritional status can be compromised by other health conditions. For example, edema characteristic of some forms of malnutrition and other disease states can conceal wasting by increasing body weight. Head circumference can be used in children 36 months and younger to monitor brain growth in the presence of malnutrition. Brain growth is better spared than either height or weight during malnutrition.

To interpret anthropometric data, they must be compared with reference data. The choice of the appropriate reference has been discussed by Johnston and Ouyang.

Because well-nourished children in all populations follow similar patterns of growth, reference data need not come from the same population as the children of interest. It is of greater importance that reference data be based on well-defined, large samples, collected in populations that are healthy and adequately nourished. Reference growth charts (Kuczmarski et al., 2002) have been compiled from cross-sectional data collected from population surveys of U.S. children. These have been adopted as international standards by the World Health Organization.

### **Choosing a Dietary Approach to Nutritional Status Assessment**

Several techniques exist for collecting dietary data with which to estimate nutritional status. Because these techniques vary in cost for data collection, burden on the respondent, and which aspects of diet they are designed to measure, it is important to clearly articulate the goals of dietary assessment of nutritional status before choosing an assessment strategy.

The primary consideration in choosing a dietary assessment method is the specific type of data needed. Is the research intended to document intake of “foods” or of “nutrients”? If the answer is foods, the method must take account of the population’s foodways. These include variability in food intake patterns (for example, day-to-day, seasonal, ritual cycles); differences in food consumption by sex, age, and ethnicity; and what items the population considers to be legitimate “food.” If the objective is to measure nutrient intake, the method must take into account several additional factors: food preparation techniques, including the addition of condiments and the effects of the technique on nutrient composition of the food; sources of error in the determination of amounts of foods consumed; differentiation distribution of nutrients among foods; and the contribution of “non-food” consumption (such as betel nut, laundry starch, and vitamin and mineral supplements) to total nutrient consumption.

Another important consideration is the time period the data are intended to represent. If the period is a relatively discrete one, it may be possible to document diet quite precisely. However, if the interest is in measuring “usual” diet, the methods must allow this abstract concept to be estimated statistically.

Population measures of dietary status can be derived either from data describing the entire population or population sub-group, or from data describing samples of individuals. Population-wide data include food availability figures, which allow the assessment of food balance—the amount of food produced or imported by a population less that exported or used as nonhuman food. Such measures are necessarily crude, as they do not measure consumption directly. Another approach to measuring dietary status of groups has been to focus on the household. Indirect data on household food intake can be derived from records of foods brought into the household or from

pantry inventories. Because of variations in intrahousehold distribution of foods, such techniques cannot be used to estimate individual intakes.

By far the most precise way of measuring dietary intake is to gather data on individuals. These methods depend on identifying a period of time for which data are needed, measuring food quantities consumed, and then translating these into nutrient amounts, either through direct chemical analysis or (more commonly) using food composition tables.

### Common Methods for Dietary Data Collection

The most valid, or accurate, dietary methods are prospective methods. These involve keeping records of foods consumed over the period of time of interest. This can be done by individuals themselves, or by others observing them. Sometimes the foods are weighed before eating and then plate waste is weighed and subtracted. A similar method is to prepare two duplicate meals; one is consumed by the subject and the other is analyzed for nutrient content. Another method is the dietary record, in which the subject records estimated amounts of foods consumed. In any case, these methods are highly reactive because individuals may alter usual behavior to make their diet more socially desirable or to simplify the process of record keeping.

Recall methods are the most widely used type of dietary data collection method. They are less reactive, but also less accurate than record methods. Twenty-four hour recalls, in which the previous day's intake is queried in detail (for instance, foods, amounts, preparation techniques, condiments) are easiest for individuals to complete. The data reported are converted from foods to nutrients with the use of food composition tables. Because a single day is not representative of usual intake, multiple twenty-four hour recalls are frequently used. These multiple recalls can be thought of as sampling from an individual's ongoing food behavior. The number necessary to reliably measure diet depends on the nutrient of interest. Nutrients widely distributed in food (such as carbohydrates) require fewer days than nutrients not widely distributed (such as cholesterol). The number of recalls needed also depends on the nature of the diet. In societies where day-to-day and season-to-season food intake varies, more days are needed than where diets are more monotonous.

The semiquantitative food frequency is a recall method in which an individual summarizes the diet to produce a measure of usual intake. For a list of foods commonly eaten, the individual estimates how frequently the food has been eaten in the time period in question (often, one year) and in what amount. Food composition tables are then used to estimate the usual daily intake. This method combines low burden on the individual with low cost. It has been widely used and studied, as it is the foremost method used in nutritional epidemiology. Research has examined how best to formulate a list of foods,

how to present the foods to the subject, and whether portion sizes should be included.

Because the act of estimating frequency of intake is assumed to be based on cognitive processes, research has examined how best to maximize reliability and validity of food frequency data by focusing on the cognitive tasks experienced in the course of completing a food frequency questionnaire. This includes questions such as whether a long list of individual foods should be presented (for example, skim milk, 2 percent milk, whole milk) or whether foods should be nested (for example, questions about the presence or absence of milk in the diet separated from the variety of milk). The results of these analyses have been mixed but suggest that incorporation of formatting changes based on cognitive theory will enhance the accuracy of reporting.

There has also been recent discussion of the actual task of summarizing and estimating intake experienced by the subject. The traditional explanation that persons completing a food frequency questionnaire actually retrieve and integrate past behavior to achieve an average dietary intake has been challenged by arguments that persons answer food frequency questionnaires in terms of a composite image of themselves and their diet, rather than a statistical estimate. If the latter is the case, one might expect that attempts to minimize error will reach a threshold of error that is unlikely to be crossed without a major conceptual shift in dietary data collection techniques for nutritional status assessment.

**ASSYRIA, ANCIENT.** *See Mesopotamia, Ancient.*

**AUSTRALIA AND NEW ZEALAND.** Australasian neighbors, once part of the same vast land mass known as Gondwanaland, Australia and New Zealand share a similar recent history. Both were British colonies settled largely by emigrants from England, Scotland, and Ireland, and both experienced rapid agricultural expansion in the 1800s. The initial prosperity of both was built on primary production, a high proportion of which—wool, meat, wheat, dairy products, fresh fruits such as apples and pears, and dried fruits such as raisins, sultanas, and currants—was exported, principally to Britain (until the formation of the European Economic Community).

One significant difference between the two countries is in their indigenous populations; the original inhabitants of Australia, for over forty thousand years before white settlement, were nomadic hunter-gathering Aborigines, while in New Zealand the first people were relatively stable semiagrarian communities of Maoris who arrived from eastern Polynesia in the seventh or eighth century. Both groups exploited indigenous food resources, but the Maoris also brought with them plant foods such as yams, taro, and kumara (sweet potato), which they cultivated.

## Early Colonial Food and Cooking

The convict colony of New South Wales, founded in 1788, was at first heavily reliant on imported rations. Gradually, however, emancipated convicts and free settlers, many with farming experience, settled the land, often establishing orchards and gardens around the homesteads and becoming largely self-sufficient. These initial farming experiences benefited later colonies, including New Zealand.

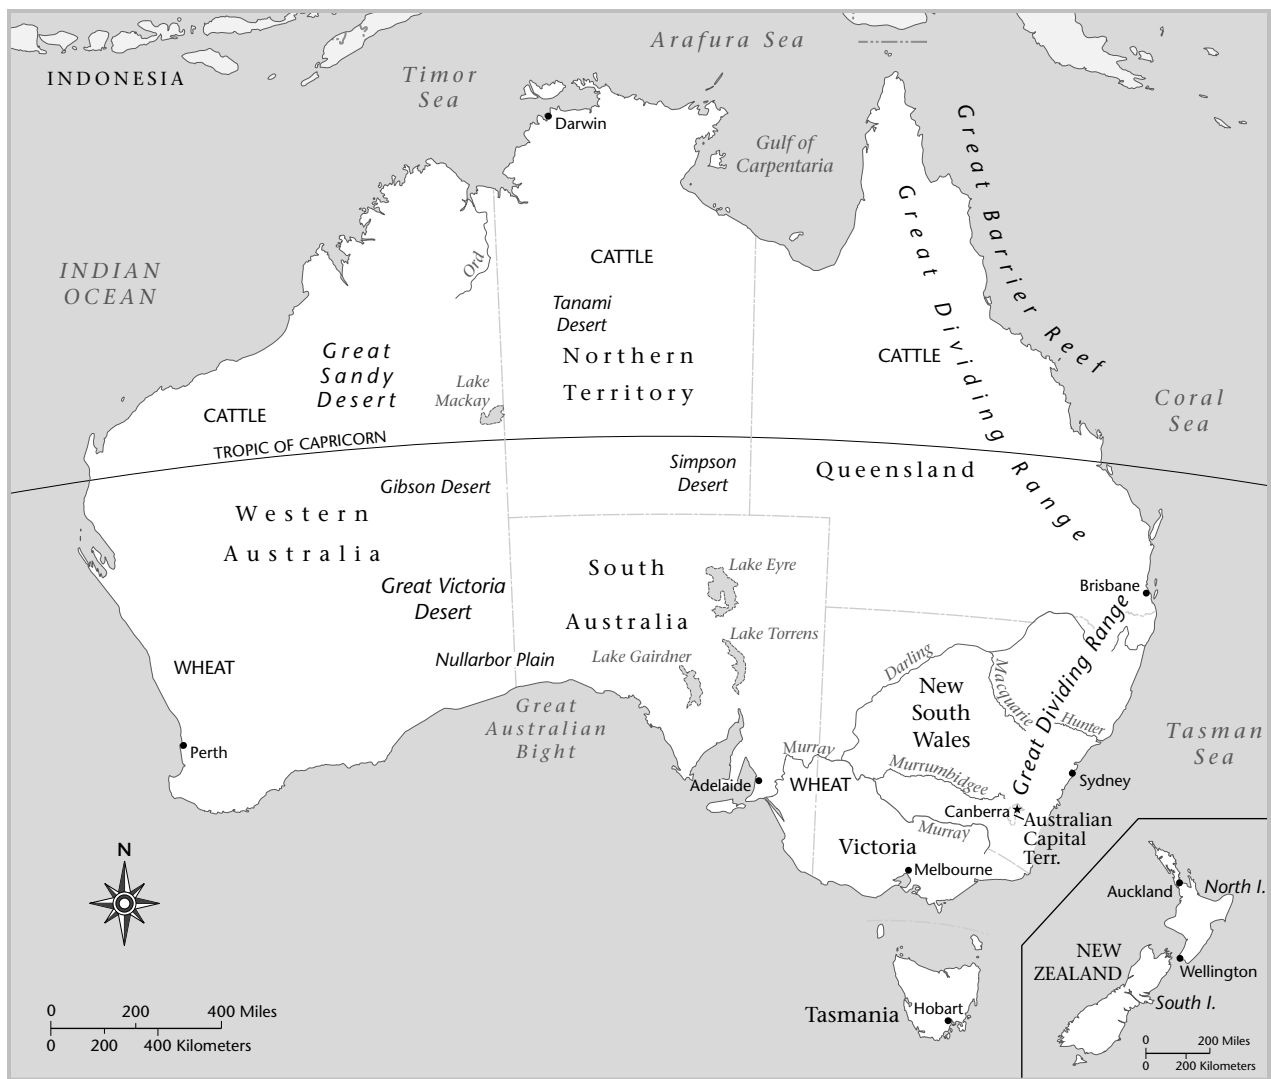

The success and profitability of sheep grazing, which saw sheep numbers in New South Wales increase almost fivefold between 1803 and 1813, meant that meat was abundant and very cheap in the colonies, and a pattern of "meat three times a day" was firmly established by the 1840s. The standard weekly ration for Australian farm laborers in the 1830s was ten pounds of meat, ten pounds of flour, two pounds of sugar, and four ounces of tea.

Mutton, tea, and damper formed the basis of a sustaining, if monotonous, diet for many rural workers. Damper was a yeastless substitute for bread, made of flour, salt, and water and cooked in the embers. In *A Summer at Port Phillip* (1843), Robert Dundas Murray wrote: "You have mutton and damper today,—mutton and damper will appear tomorrow, and from that day till the end of the year, your dinner is mutton, boiled, roasted or stewed." Even in landowners' homesteads, mutton was ubiquitous. It was generally cooked as Robert Dundas Murray described, but in both Australia and New Zealand at least one new dish became popular—Colonial Goose, a roasted boned leg or shoulder of mutton with a sage-and-onion stuffing.

In both Australia and New Zealand, the early white settlers made only limited use of the indigenous food resources, preferring to choose those foods that resembled familiar fare. Seafood, including the oysters of Sydney harbor, and shellfish such as *toheroa* and *paua* (abalone) in New Zealand, were readily accepted and eaten, as were freshwater fish and crustaceans. In Australia kangaroo was rated equal to hare and venison, and kangaroo tail soup was often featured on menus; game birds such as quail, pigeon, duck, and wild turkey were also hunted and eaten. Of the vast range of plant foods consumed by the indigenous inhabitants, only a few, such as native fruits made into preserves or desserts, appeared on colonial tables.

## Urban Lifestyles

The gold rushes of the mid-nineteenth century brought great prosperity, especially to the cities, which, by the 1870s, could boast sophisticated restaurants and a wide range of imported luxury foods, from caviar to Gorgonzola cheese. In domestic kitchens, however, plain, homely, English-style cooking prevailed, though with local adaptations. The roast (or baked) dinner serves as an example of how Australia and New Zealand developed their own variations of English traditions; the joint, beef or lamb, was baked in the oven with drippings, sur-

rounded by a variety of vegetables—the obligatory potatoes and pumpkin, plus onions, parsnips, orange-fleshed kumara in New Zealand, sometimes carrots, and white-fleshed sweet potato—and served with gravy and a green vegetable, usually peas or beans.

By the turn of the century food was no longer cooked in the hearth but on wood-burning ranges or, in the cities and large towns, gas stoves, which were introduced in the 1870s. Ice chests were also becoming common at this time, favoring the growing popularity of cold puddings such as jellies, flummeries, and molded custards which also took advantage of commercially manufactured gelatin.

Large quantities of meat were still being eaten, despite success with the first shipment of frozen meat from Australia to England in 1880 and subsequent development of a profitable export trade, and despite increasingly loud denunciations of overconsumption of meat by the medical profession. The Sydney physician Dr. Philip Muskett, in particular, railed against the eating habits of a nation of meat worshipers and tried to persuade Aus-

tralians to adopt a diet more appropriate to the climate by eating more vegetables, particularly salads. At this time, according to the evidence of recipe books, vegetables were typically overcooked and salads rare; tomatoes did not become popular until the 1880s and even then tended to be cooked rather than eaten raw.

Most Australian and New Zealand households at the end of the nineteenth century began the day with a substantial breakfast: porridge, bacon and eggs, sausages or chops (particularly on farms that raised their own meat), toast or bread, tea or coffee. Dinner, the principal meal, was often served in the middle of the day and was centered on the main course of meat and vegetables, sometimes preceded by soup, and followed by dessert of some sort—a hot or cold pudding, custard, tart, or pie. (See the menus sidebar.) The evening meal generally featured meat again, but was less substantial. In cities and towns dinner was often eaten in the evening, after the return from work of the (male) head of the household, and the midday meal, lunch, was reduced to sandwiches and fruit

or to the quasi-national dish of both countries, the meat pie (accompanied by tomato sauce).

### Scones, Sponges, and Afternoon Teas

In addition to the three daily meals was afternoon tea, which could be particularly lavish on Sundays. Until about the mid-twentieth century, afternoon tea was the

accepted way of entertaining guests; it was a particularly feminine form of entertaining, and gave women the opportunity to display their flair and imagination.

Many of the dishes that Australians and New Zealanders claim as their own belong to the world of the afternoon tea. Adapting a British tradition, Australians developed pumpkin scones (with the addition of mashed pumpkin) and fried scones. Lamingtons, cubes of butter cake coated with a thin chocolate icing and rolled in desiccated coconut, were invented in the early 1900s. Anzac biscuits, made with rolled oats, flour, coconut, butter, sugar, and golden syrup, and named after the forces that served in World War I, are common to both countries, as are afghan biscuits, melting moments, and hokey pokey biscuits. Cooks in both Australia and New Zealand specialize in light, airy sponge cakes, often served as a four-inch-high sponge sandwich filled with jam and cream.

Another antipodean invention is the Pavlova, a crisp-shelled, soft meringue cake spread lavishly with whipped cream and decorated with fresh fruit, such as strawberries or passion fruit pulp. Its origins are still disputed, but it seems likely that the cake originated in New Zealand, even if today's standard recipe reflects a later Australian version.

### Multicultural Influences

In both Australia and New Zealand, postwar food and eating reflects multicultural influences. Since the 1960s, increasing numbers of Australians and New Zealanders have traveled in Europe and Asia and experienced different cuisines, while at the same time an influx of immigration, particularly from Mediterranean countries—Greece, Italy, the former Yugoslavia, Turkey, and the Middle East—has resulted in the availability of a vast diversity of foods and restaurants. Many Vietnamese settled in Australia at the end of the conflict in that country, further diversifying the range of Asian foods and ingredients available. The tropical city of Darwin, in particular, has a large population of Asian and Pacific Island peoples whose foods and cuisines can be sampled at the weekly (in the dry season) Mindil Beach Market. Among successful “new” foods are Cervena (farmed deer) in New Zealand and kangaroo in Australia, harvested in the wild under license. New Zealand has also effectively commercialized the kiwifruit, a fruit of Chinese origin (and formerly known as the Chinese gooseberry) imported into New Zealand in the early 1900s.

The changes in eating habits since around 1950 demonstrate a convergence of different trends. Supermarkets have replaced individual specialists and convenience foods—prepared soups and sauces, instant cakes and puddings, frozen pastries and ice creams—have largely replaced the raw ingredients from which such dishes used to be made. Relaxation of licensing laws, together with greater appreciation of wine, led to a blossoming of restaurants, often run by immigrants; today's opportunities for dining out range from silver-service

restaurants to casual cafés to fast-food franchises. Thanks to both the food manufacturing industry and restaurants, people are familiar with a wide range of cuisines, both European and Asian. Emphasis on the links between health and eating has made people increasingly aware of dietary advice. Finally, a greater recognition of vegetarianism is obvious, with most cafés and restaurants including vegetarian options in their menus.

Domestic menus, while becoming more simplified, also show the influences of many different cuisines and a willingness to accept nonmeat meals. (See the menus sidebar.) Meat consumption declined dramatically in the 1970s when the cholesterol–heart disease connection was announced, though the cooked breakfast had already begun to wane in the presence of a proliferation of ready-to-eat breakfast cereals. In Australia the consumption of meat is less than two-thirds what it had been one hundred years earlier, and consumption of lamb and mutton has halved. In fact, there is more chicken, and almost as much pork, eaten as lamb and mutton (both chicken and pork are the products of intensive factory farming).

The last years of the twentieth century also saw greater awareness of indigenous food resources, such as the Australian flavorings of lemon myrtle and native pepper leaf, which are increasingly used in restaurants and by the food industry.

**AUSTRALIAN ABORIGINES.** Australian Aborigines are believed to have first arrived in northern Australia forty to sixty thousand years ago. They gradually spread throughout the continent, adapting to a vast range of environments from coastal tropics to inland desert, from temperate grasslands to mountainous highlands and riverine plains. In view of the diversity of plant and animal resources available in such a variety of settings, it is difficult to generalize about Aboriginal food, diet, and cooking practices. Nevertheless, some fundamental features were common to virtually all of the five hundred “tribes” or language groups believed to have been living in Australia at the time of European settlement at the end of the eighteenth century.

#### Hunter-Gatherers

Aborigines practiced a highly mobile hunter-gatherer lifestyle, moving frequently from place to place in accordance with seasonal availabilities of food resources. At the same time, they manipulated the environment in such a way as to favor certain species of flora and fauna. Their management of the land and its resources included setting light to dry grass and undergrowth in specific areas at certain times of the year in order to drive out small animals that they could easily capture. This practice has since been termed “firestick farming.” It had a secondary benefit in that the new green growth which followed rain attracted small marsupials and other animals to the area, thus ensuring food supplies.

Typically, men hunted large game such as kangaroos and emus, and speared, snared, or otherwise procured smaller animals (opossums, bandicoots), birds (wild ducks, swans, pigeons, geese), and fish. Men tended to operate individually, while groups of women and older children collected plant foods (fruits, nuts, tubers, seeds), small game such as lizards and frogs, and shellfish. There were variations to this pattern; around coastal Sydney, the principal food-gathering task of women was fishing, and men also collected vegetables. The relative contributions of men and women to the communal meal varied according to season and location, but women's gathering activities could provide from 50 to 80 percent of a group's food. The time taken to collect a day's food varied similarly, but rarely would it have occupied the whole day.

The Aboriginal diet was far from monotonous, with a very wide range of food resources exploited. In northern Australia, thirty different species of shellfish were

collected throughout the year from seashore and mudflats; in Victoria, about nine hundred different plant species were used for food. Whatever the available resources, Aborigines did not always and necessarily eat everything that was edible; in some coastal regions fish and sea animals were preferred as sources of protein, and land animals were relatively neglected. On the other hand, Tasmanian Aborigines ate lobsters, oysters, and other shellfish but did not eat scaly fish; they avoided carnivorous animals and the monotremes platypus and echidna, though in other regions echidnas were eaten.

Tools were basic: a digging stick for women, spear and spear thrower for men. Fish, birds, and small game could be caught in woven nets or in conical basket traps. Many Aboriginal groups used lines, with crude shell or wooden hooks, to catch fish; alternatively, fish traps were sometimes constructed in rivers and along the coast to entrap fish, or temporary poisons were placed in waterholes to stun fish or bring them to the surface.

### Food Distribution and Taboos

Complex rules determined food sharing arrangements. Men were usually treated preferentially in the distribution of game, with the hunter distributing the various portions among his male relatives who might then pass some to the women; if the hunter himself had a share it was an inferior cut. Offal—heart, liver, kidneys, brains—tended to be particularly prized, and often went to senior men. Women's gathering was for themselves and their immediate family rather than for the whole group, and there were certain plant foods that men apparently ignored.

Because of Aboriginal spiritual beliefs that people, plants, animals, and, indeed, the land are all part of a system created by ancestral spirits, all united and having equal rights to the resources of the country, totemic relationships existed between human and nonhuman species. The rules governing these relationships varied; for some groups killing and eating the totem was always taboo, while for others it might have been prohibited only

at specific times or in special ceremonies. Thus some language groups of Aborigines may not have eaten emu while neighboring groups did.

Particular taboos, usually involving animal foods, applied to women during pregnancy or lactation, to young girls at their first menstruation, and to young boys at the time of their initiation. Wallaby and two species of bandicoot were sometimes forbidden to girls, because they would cause premature puberty, and to young boys, because they would favor brownish rather than black beards. Some foods, such as bitter tubers, were prohibited to children but sweet foods, such as plant galls and the edible gums that exude from kurrajong and other trees, were regarded as special treats and preferentially left to the young.

### Food Preparation and Cooking

Many fruits and nuts and a few plant foods could be eaten raw and did not require cooking, but generally roots, bulbs, and tubers were roasted in hot ashes or hot sand. Some required more or less lengthy preparations to improve their digestibility or, in some cases, to remove bitterness or leach out quasi-poisonous components. In the central Australian desert, Aborigines relish the honey sucked from the distended bellies of underground worker ants; in effect, these "honey ants" serve as live food stores for other worker ants.

The principal means of removing toxins were pounding, soaking, and roasting, or a combination of any of these. One particular variety of yam, *Dioscorea bulbifera*, was subjected to a series of treatments to remove bitterness. First it was scorched to shrivel the skin, which was removed; then it was sliced and the slices coated with wet ashes and baked in a ground oven for twelve hours or more, and the ashes were then washed off before eating.

The kernels of the cycad palm (*Cycas armstrongii*), highly toxic in their unprocessed state, were treated by pounding, soaking in still or running water until fermented, and pounding again between stones to produce a thick paste that was cooked in hot ashes, sometimes wrapped in paperbark, yielding a kind of damper or bread.

Aborigines did not have sophisticated cooking equipment; basic culinary techniques included baking in hot ashes, steaming in an earth oven, or roasting on hot coals, this last method typically used for fish, crabs, small turtles, and reptiles. Oysters, too, were often cooked on hot coals until they opened, but in northern Australia large bivalves were "cooked" by lighting a quick fire on top of the closely packed shells arranged on clean sand, hinge side uppermost.

Cooking in hot ashes was the most common method of preparing tubers, roots, and similar plant products including yams (*Dioscorea* spp.) and the onion-shaped tubers of spike rush (*Eleocharis* spp.), both of which were important foods for Aborigines in northern Australia. Witchetty grubs (*Xyleutes* spp.) and similar grubs from other trees were also cooked in hot ashes, if not eaten

raw, as were the flat cakes, commonly called dampers, made from the seeds of wild grasses such as native millet (*Panicum* sp.). The relatively complicated preparation involved threshing, winnowing, grinding (using smooth stones), the addition of water to make a paste, then baking in the ashes. Seeds of other plants, such as wattles (*Acacia* spp.), pigweed (*Portulaca* spp.), and saltbush (*Atriplex* spp.), as well as the spores of nardoo (*Marsilea drummondii*), were treated similarly.

Earth ovens were essentially pits, sometimes lined with paperbark or gum leaves, heated with coals or large stones previously heated in a fire. Foods to be cooked were placed in the oven, covered with more paperbark, grass, or leaves and sometimes more hot stones, then enclosed with earth or sand. Roots and tubers were sometimes placed in rush baskets for cooking in an earth oven, and when clay was available, such as near the edge of a river, fish were enclosed in clay before baking.

Large game such as kangaroo and emu was gutted immediately after killing and carried back to camp where the carcass was thrown onto a fire for singeing. After the flesh had been scraped clean, the animal was placed in a pit in which a fire had previously been lit to supply hot coals, covered with more hot coals plus earth or ash or sand, and baked. The cooking time depended on how long hungry people were willing to wait.

### Ceremonial Foods

When special occasions such as initiation brought large numbers of Aborigines together, it was essential that food resources in the vicinity of the meeting place were both adequate and reliable. Ceremonial foods, therefore, were less associated with particular qualities than with seasonal abundance. In the mountainous regions of southern New South Wales and Victoria, bogong moths (*Agrotis infusa*) were profuse and easy to collect in late spring and summer, and at this time Aboriginal groups converged in the mountains where ceremonies took place. The prevalence of shell middens suggests that shellfish provided ceremonial sustenance in coastal areas. In Arnhem Land (Northern Territory) cycad nuts were plentiful at the end of the dry season, when travel was still possible, and the kernels, once heated to remove toxins, were ground to yield a thick paste, and subsequently baked in the ashes to serve as a special ceremonial food for men participating in sacred ceremonies and forbidden to women and children unless authorized by older men.

Many Aborigines today have lost touch with their foods and foodways, preferring instead the convenience of Western-style foods. Nevertheless, recognition of the health benefits to Aborigines of their traditional diet has resulted in active encouragement of hunter-gatherer practices, even if only to supplement store foods. In many areas, Aborigines have special hunting and fishing rights for species that are otherwise protected or subject to limits—though today their hunting typically involves firearms rather than clubs and spears.

**AVERSION TO FOOD.** Food aversions are far more common, far more diverse both within and across cultures, and far stronger than is often realized. Examination of the characteristics and origins of food aversions can help to illustrate the many contributions of genes and environment to behavior. Further, an understanding of food aversions can be useful in understanding, as well as treating, many eating and drinking disorders.

### Classification of Food Aversions

Food aversions have been classified into four types: foods that are rejected because they are dangerous, inappropriate, disgusting, or distasteful. We consider foods to be dangerous, and therefore do not eat these foods, if eating them has previously resulted in physical harm, or if eating these foods is reputed to cause physical harm. However, a dangerous food, such as poisonous mushrooms, would be eaten by someone if there were some medication to prevent any illness from occurring.

Inappropriate foods are items that we consider not to be food. An example of an inappropriate food would be Kentucky bluegrass. Although deer and other herbivores might eat this grass, we would consider it inappropriate for humans to do so. Similarly, there may be an item, such as a particular kind of berry, that is considered to be a food by one culture but not by another.

There are several reasons why someone might treat an item as an inappropriate food. One involves the taste of the item. From birth, humans find certain tastes, notably the taste of bitter, to be aversive, and therefore may not consider items with those tastes to be appropriate foods. For example, many wild plants taste extremely bitter. Given that poisonous plants are often bitter, scientists believe that humans who avoided bitter tastes were more likely to survive and therefore humans evolved to have an innate aversion to bitter tastes. Direct experience with an item may also contribute to its classification as an inappropriate food; attempts to chew some wild plants can be fruitless. Finally, someone may consider an item to be an inappropriate food because of information passed on by someone else. For example, caregivers may tell children that grass is not food.

Disgusting foods are those that most of us would not want in our meals or stomachs no matter how the foods were disguised and no matter how small the amount. Some examples of items classified as disgusting foods are urine and feces. Foods can become disgusting because of someone's having observed others' reactions to these foods, because of contact of a previously nondisgusting food with something considered disgusting, or because a food looks similar to something disgusting. Thus, because most American children learn from others that insects are disgusting foods, we consider a glass of milk that used to have a cockroach in it to be disgusting, and we find fudge that looks similar to feces to be disgusting. Similarly, cultural beliefs can result in certain foods being considered disgusting. For example, many vegetarians consider meat to be disgusting, and Jews who keep kosher may find meal combinations of meat and dairy products to be disgusting.

Probably the most studied is the fourth and final category: distasteful foods. These are foods that most of us would not mind eating if the taste of the food were covered up by another taste, or if we only found out that we had eaten it after we had finished eating. An example is warm milk. Once again, an innate dislike of certain tastes can contribute to food aversions of this sort. However, many members of the distasteful food category are illness-induced food aversions (also known as taste aversions). Humans and many other species exhibit illness-induced food aversions when they eat something, become ill, and then do not want to eat that food again. This is an extremely powerful type of learning. Study of the acquisition of illness-induced food aversions has proved extremely important to the development of general learning theory, and has resulted in a number of different applications outside of the laboratory. Therefore, the following sections discuss illness-induced food aversion learning in some detail.

### **Taste Aversion Learning: Basic Observations**

Prior to scientists' conducting any investigations of taste aversion learning, farmers were aware of this phenome-

non, which they called bait shyness. The farmers found that it was difficult to kill rats by putting out poisoned bait. The rats would take only small samples of any new food, in this case the bait, and if they then became ill, they would subsequently avoid the bait.

Laboratory experiments on taste aversion learning began in the 1950s. Researchers noticed that rats eat less after being irradiated. Apparently irradiation makes rats gastrointestinally ill and they associate the illness with food, resulting in a taste aversion to the food.

In 1966 John Garcia and Robert A. Koelling used a taste aversion paradigm to show learning theorists that it is easier to learn some associations than others. In their experiment, rats more easily learned to avoid licking flavored water when that licking was followed by illness than by shock, and they more easily learned to avoid licking water accompanied by clicks and light flashes when that licking was followed by shock than by illness. Garcia and Koelling concluded that it is easier for rats to associate tastes with illness and audiovisual events with shock than vice versa. It was due to results such as these that this type of learning was labeled taste aversion learning.

Odors may also play an important role in food aversions linked to illness, yet the term "taste aversion learning" has persisted. The fact that tastes and odors are more easily associated with illness than with other sorts of events helps us to survive. The presence of a poison is more likely to be indicated by a particular odor or taste than by a particular appearance or sound.

Subsequent experiments found that taste aversion learning has some other special properties that may help animals to survive. For example, taste aversions can be acquired with up to twenty-four hours between consumption of the food and illness. This is advantageous because it may take hours before a poison will result in illness. In addition, in taste aversion learning, the taste actually seems to come to taste bad. This also helps animals to survive because a poison should be avoided no matter under what circumstances it is encountered. Finally, taste aversions are more likely to form to novel foods, and often form after just one pairing of a taste with illness. These characteristics help to ensure that, as much as possible, animals learn quickly to avoid new poisonous foods. Animals appear to have evolved so that they easily acquire long-lasting aversions to cues associated with poisonous foods.

Taste aversion learning has been studied in a great many species, including humans. Surveys have found that most college students report having acquired at least one taste aversion. In general these aversions are strong and have persisted a long time. Laboratory experiments have shown that taste aversions are acquired similarly across species.

### **Applications of Taste Aversion Learning**

Research on taste aversion learning can help us to understand, and possibly modify, many food aversions and

preferences. For example, taste aversion learning may cause what are termed specific hungers. These are preferences for specific foods containing a nutrient, such as thiamine or sodium, in which an animal's diet has been deficient. Animals may feel ill when deficient in these nutrients, and thus form taste aversions to their usual foods. New foods, or foods associated with recovery from the illness, are therefore preferred.

In a very different application, taste aversion learning has been used for wildlife management—to prevent coyotes from attacking sheep on ranches in the western part of the United States. Many ranchers choose simply to kill the coyotes. However, coyotes are a valuable part of the ecosystem (for example, by decreasing the rabbit population). Researchers reasoned that, if they could train the coyotes to avoid sheep but not rabbits, this would preserve the ecosystem. They therefore placed lamb bait laced with an illness-inducing drug on the range in areas frequented by coyotes. The coyotes appeared to acquire an aversion to eating or even approaching sheep. In fact, after aversion training, coyotes behave submissively toward sheep, running the other way when a sheep approaches.

Taste aversion learning has also been helpful in understanding the life-threatening anorexia that can accompany cancer. Some cancer treatments, such as radiation and chemotherapy, can cause gastrointestinal illness. When this illness is paired with food consumption, taste aversions can result. Ilene L. Bernstein and Mary M. Webster gave child and adult patients a novel-tasting ice cream prior to their chemotherapy and the patients acquired an aversion to that ice cream. These findings and others have resulted in the development of the "scapegoat technique." This technique involves giving cancer patients a novel food along with some familiar food just prior to their chemotherapy. The patient forms an aversion to the novel food and not to the familiar, usual food.

Although it might seem that taste aversion learning could be useful in decreasing overeating, it is not employed for this purpose. Taste aversions form to specific foods, and it is too easy for a patient to switch to overeating a different food once an aversion has been acquired to a previously overconsumed food.

In contrast, taste aversion learning has been successfully employed in treating alcohol abuse, although the pairing of alcohol and illness must be done carefully in order for strong taste aversions to develop. In addition, it is necessary for illness to be paired with a variety of alcoholic beverages in order to ensure that an alcoholic does not switch to new alcoholic beverages following aversion training.

## Conclusion

There are a great many different types of food aversions in humans and other animals. Some of these aversions help animals to survive, and others can be extremely debilitating. Continuing research will help to maximize the

Martin E. P. Seligman (president of the American Psychological Association in 1998) has described how, in 1972, he ate sauce béarnaise on steak and then became ill with what was definitely stomach flu (his colleague at work who had not eaten the steak came down with the same affliction, and his wife who had eaten the steak did not). Yet, even though he was absolutely convinced that the sauce béarnaise did not cause his illness, Seligman acquired an aversion to it.

\*

Some children and pregnant women repeatedly consume nonnutritive substances such as paint, plaster, and dirt. Because such food cravings are most likely to appear in people who need a lot of nutrients, it has been proposed that these cravings are the result of specific hungers for minerals such as iron.

positive effects of these aversions, and minimize their negative effects.

**BABY FOOD.** The consumption of food is an extraordinarily social activity laden with complex and shifting layers of meaning. Not only what we eat but how and why we eat tell us much about society, history, cultural change, and humans' views of themselves. What, when, and how we choose to feed infants and toddlers, the notion of "baby food" as opposed to "adult food," and whether or not these foods are nourishing and satisfying reveals how mass production, consumption, and advertising have shaped attitudes about infancy and corresponding parenting philosophies and practices. From the late 1920s to the postwar baby boom of the 1950s, mass-produced solid infant food, especially fruits and vegetables, shifted items of rarity into a rite of passage, a normal, naturalized part of an infant's diet in the United States. In the early twenty-first century commercially produced infant food not only remained a mainstay of an infant's diet in the United States but manufacturers also sought new markets, including developing countries.

### **Preindustrial First Foods**

Historically, semisolid mixtures of grains and water, animal milk, or broth, variously known as "pap," "panada," or "gruel," have been the first semisolid food (also known as "beikost") an infant receives. (Cone, 1984, p. 12; Quandt, 1984). In many cultures mothers chew food, making it similar in consistency to gruel, then feed it to their infants. The earliest known infant feeding devices date back to the second or third centuries, though few specifics regarding their use are understood (Fildes, 1995, p. 116). Commonly infants have been introduced to pap mixtures as a supplement to breast milk. The pap then becomes an increasingly prominent part of infants' diets until they are completely weaned, which varies from several months old to three to four years of age.

### **Mass-Produced Baby Food**

The industrialization of the food supply laid important groundwork for dramatic changes in infant feeding. By the 1920s in the United States canned goods were mass-produced in sufficient quantity to be affordable for most, allowing Americans to consume, among other things, more fruits and vegetables year round. Also at this time the discovery and promotion of vitamins helped change Americans' wary attitude toward fruits and vegetables.

These foods previously were not fed to children before two or three years of age as they were thought to cause cholera and dysentery.

Thus the market was ripe for the introduction of commercially canned food for babies, especially produce. In 1928 the Michigan-based Fremont Canning Company, owned by the Gerber family, began producing strained vegetables for infants, which proved so successful that the company changed its name to the Gerber Products Company and became the exclusive maker of baby foods. By 1935 Gerber's biggest competitors, Beech-Nut, Heinz, and Libby's, entered the baby food market. Despite these competitors' quick development of their own mass-produced strained baby foods, Gerber managed to maintain its dominance of the market (Nisbet, 1954). Mothers, both those at home full-time and those with paid employment, embraced and benefited from commercially prepared solid infant food, and within a matter of decades the product became a common part of an infant's diet. The easy availability of, prominent advertising for, and increasing use of commercially prepared infant formulas acclimated mothers and doctors alike to infants' ingestion of substances other than breast milk.

### **Increasingly Earlier Introduction of Solids**

In the late 1920s, just as Gerber began its national advertising and distribution of canned baby foods, the prevailing wisdom advocated introducing strained fruits and vegetables around seven months. The market for baby food increased with the idea that babies could eat solids, especially fruits and vegetables, at an earlier age. During the 1930s the recommended age was four to six months, and by the 1950s it was four to six weeks, with some doctors advocating feeding infants strained cereals and vegetables within days of birth. As this early introduction of solids became standard advice and practice, solid baby food, like infant formula, functioned not only as a supplement to but as a substitute for breast milk.

### **Commercial Baby Food: Modifications over Time**

While mass-produced baby food increased infants' year-round consumption of fruits and vegetables and provided a welcome efficiency in preparation, it also had its deficiencies. Throughout most of the twentieth century commercially canned baby food was overcooked and

contained added salt, sugar, starches, fillers, artificial preservatives, and even, though infrequently, dangerous contaminants, such as lead, glass shards, or pesticides. Moreover until the 1990s baby food manufacturers did not have to list the precise percentage of each ingredient on the label (Stallone and Jacobson, 1995).

Mass-produced baby food was created and became successful in response to an emerging industrialized society, meeting the needs of changing work patterns and an increasingly fast-paced lifestyle. It remained a rite of passage for most American babies at the advent of the twenty-first century, though with modifications. During the 1970s the return to breast-feeding and the renewed popularity of homemade baby foods were products of the public's more skeptical attitude toward corporate capitalism and institutions in general. In the 1980s and 1990s, mostly in response to consumer demand, baby food manufacturers eliminated sugar, salt, and modified starch from most products, introduced organic lines, and eschewed the use of any foods containing genetically modified organisms. Because of an overall declining birthrate in the United States at the beginning of the twenty-first century, baby food manufacturers, to maintain and even increase market share, began to forge new markets, targeting Latino and African American populations in the United States and trying to expand market share in developing countries around the globe.

**BAGEL.** A specialty of East European Jews, the classic bagel is a small ring of dough made of white flour, yeast, and water. The dough is first boiled and then baked.

#### The Bagel in Europe

According to Mordecai Kosover in *Yidishe maykholim*, the earliest mention of the bagel is in the 1610 statutes of the Jewish community of Cracow, which state that it is permissible to make a gift of bagels to the woman who has given birth, the midwife, and the girls and women who were present (Kosover, p. 129). Even earlier sources indicate that the father would send *pretzn*, or pretzels, which are historically related to the bagel, to everyone on the occasion of a circumcision. Legends that trace the first bagel to the Ottoman siege of Vienna in 1683 are apocryphal. The very same story is told about the origin of the croissant, the pretzel, and the coffeehouse.

A relatively affordable treat, the East European bagel was portable and small. According to a Yiddish proverb, only by the third bagel would one feel full. Bagels made with milk or eggs were known from at least the nineteenth century, and almond bagels were among the prepared foods exchanged on the holiday of Purim. Bagels and other round foods were eaten before Tisha B'av, a fast day commemorating the destruction of the Temple, and in the twenty-first century bagels are served after a funeral and during the seven days of mourning that follow. The round shape symbolizes the round of life. The *beuglich* described in Israel Zangwill's *Children of the Ghetto* (1892) as "circular twisted rolls" suggest the *obwarzanek*, a twisted, fresh ring pretzel dating from the Middle Ages and still sold by street vendors in Poland and the large twister bagels sold in Toronto in the twenty-first century.

#### The Bagel in the United States

The bagel arrived in the United States with Jewish immigrants from eastern Europe at the end of the nineteenth century. From the 1890s until the 1950s bagel bakers struggled to form their own union, a process that began in 1907 with the establishment of a benevolent society for bagel bakers. With the influx of younger and more radical immigrants after World War I, the process of converting the benevolent society into a union intensified. Local 338, the International Beigel Bakers Union of Greater New York and New Jersey, coalesced in 1925

and was finally recognized as an autonomous local in 1937. Thanks to the union, bagel bakers in the New York metropolitan area won the best working conditions in the baking trade.

While radical in their politics, these bakers were conservative in their craft. Bagel bakers resisted technology because mechanization of the rolling process would eliminate jobs. As a result the bagel industry in the New York metropolitan area was one of the last of the baking industries to become fully automated. As late as the 1960s bagels were still made by hand in small bakeries by Jews for Jews, and Local 338 controlled the industry. Water bagels plain or salted were the basic varieties.

From 1955 to 1984 bagel bakeries outside New York and outside the jurisdiction of the bagel bakers' union found ways to distribute this highly perishable product far beyond the freshness radius of the bakery. They modified the dough, introduced flavors, packaged bagels in plastic bags, froze them, and shipped them to groceries and supermarkets across the country. Frozen bagels were marketed primarily to non-Jews. Once the bagel was packaged, it could be branded. The bagel began its shift from a generic product to a branded commodity.

With distribution channels in place and demand growing, the bagel industry was ready to increase production. Thompson Bagel Machine, which had been in development since World War I, was patented in 1960 by the Thompsons, an East European Jewish family in Los Angeles. In 1963 the first automated bagel-forming machines were introduced in New Haven, Connecticut; Buffalo, New York; and St. Louis, Missouri. As the growing bagel industry outside New York started penetrating the New York market, the union weakened and automation entered, thereby transforming the bagel baking business and fueling its exponential growth. By 1984 Lender's Bagels, which started as a family bakery in New Haven in 1927 and was the first to use a bagel-forming machine, had become so successful that it was acquired by Kraft and then Kellogg, who saw the bagel outpacing and even supplanting croissants, doughnuts, cereals, and other breakfast foods.

### The Bagel Boom

The bagel has become one of the fastest-growing sectors of the food industry. The bagel industry, with relatively low barriers to entry, has attracted a wide range of people. H&H Bagels, the icon of the New York bagel, has been owned by Herman Toro, who was born in Puerto Rico, since the 1970s. Hand-rolling is largely a specialty of Egyptian and Thai immigrants. During the 1980s, with growing national awareness of the bagel and the introduction of bagel-steaming equipment, the developing bagel category became dominated by rapidly expanding chains, franchises, and privately held as well as publicly traded bagel companies. By the mid-1990s the bagel boom peaked, and a shakeout followed. Some of the companies that grew fastest showed the most serious losses.

The bagel as Americans know it today evolved in the Jewish community in the United States. It has also become an icon of New York food, especially the onion bagel shown here.

PHOTO BY ANDRÉ BARANOWSKI.

Meanwhile the bagel had spread to such places as Germany, Turkey, Japan, Taiwan, Australia, and Bali.

### The Bagel as Icon Food

After the Holocaust American Jews came to identify the bagel with the Old World and with immigrant Jewish culture. The bagel became a lightening rod for their ambivalent feelings. While Irving Pfefferblit declared in "The Bagel" that "the Jewish bagel stands out like a golden vision of the bygone days when life was better," upscale Miami hotels during the 1950s served lox on English muffins or tartines rather than on lowly bagels (Pfefferblit, p. 475).

With the suburbanization of Jews and secondary migration of Jews to California and Florida during the post-war years, the bagels and lox brunch became a Sunday morning ritual with its own equipment, including bagel slicers and decorative bagel platters with compartments for smoked salmon, cream cheese, butter, olives, radishes, and slices of onion and tomato. So important did this meal become that "bagel and lox Judaism" became a metaphor for the gastropoetry of suburban Jews.

The close identification of the bagel with New York City arises in no small measure from its labor history,

though some claim the secret to the New York bagel is the water. Paradoxically the further the bagel traveled from New York, the more it became identified with New York and with all that is metropolitan and cosmopolitan. However, other cities with large Jewish communities also have long bagel histories and distinctive bagels. The Montreal bagel has a narrow coil and a big hole. It is rolled by hand, boiled in water sweetened with honey, sprinkled with sesame seeds, and baked in a wood-fired oven, which gives it a slight smokiness.

### Bagel Innovations

New bagel eaters with no prior loyalties are a prime market for bagel innovations. With but a few concepts (size, shape, flavor, topping, stuffing, and carrier or platform), it is possible to produce combinations, permutations, and improbable hybrids. The early Lender's frozen bagels weighed two ounces. Bagels in the twenty-first century range from three to more than five ounces. There are cocktail minibagels and overstuffed party bagels the size of a tire. Così recently introduced the squagel, a square bagel. Where there were once only a few varieties (poppy seed, pumpernickel, and eventually cinnamon raisin), by the twenty-first century there were unlimited flavors (from cranberry granola to piña colada), toppings (everything from poppy seeds, sesame seeds, caraway seeds, and garlic to streusel), and fillings (from cream cheese to bacon and eggs).

At bagel shops offering twenty types of bagels, which is not uncommon, and even more varieties of spreads and fillings, customers can create hundreds of combinations. Bagel eaters from birth tend to be disdainful of what might be called the random bagel effect. "Turkey, tomato, sprouts, avocado, and cream cheese on a peanut butter and chocolate chip bagel" at Goldstein's Bagel Bakery in California is an ungrammatical culinary sentence for those fluent in the language.

The bagel replaces bread, pizza, croissant, and tortillas as the preferred carrier or platform for their fillings and toppings. New hybrid bagel products include the *bagelwich* (bagel plus sandwich), *bragel* (bagel plus roll), *bratzel* (bagel plus pretzel), *fragel* (fried bagel), and *flagel* (flat bagel) as well as the Bageldog, pizza bagel, UnHoley Bagel (ball injected with cream cheese), bagel chips, bagels for birds and dogs, and bagel bones for people. The bagel is distilled into a flavor of its own for bagel-flavored rice cakes and matzoh.

The bagel has become not only a platform for other foods but also a carrier for meanings and values as diverse as those who eat them. For many it is an icon of East European Jewish culture, for others it is quintessentially New York, and for many around the world, including in Israel, it is American.

**BAHÁ'Í.** Originating in Persia in the mid-nineteenth century, the Bahá'í Faith is the youngest of the independent world religions. It is also one of the fastest growing and most widespread of religions with about 7 million adherents in over 220 countries. Founded by the prophet Bahá'u'lláh, the faith is built on the fundamental principles of unity and justice and the necessary convergence of spiritual and social development. The faith embraces a concept of progressive revelation that assigns equal status to previous prophets, who are known as "manifestations of God." There is only one God. As perfect reflections of God the manifestations occupy a status between the human and the divine. Each prophet brings the same core message as well as new teachings suited to the time and place of his particular revelation and the stage of development of humanity. Bahá'u'lláh's purpose, as the latest of these manifestations of god, is to usher in a new world order of peace and prosperity for the human race.

Dietary codes and prohibitions are absent in the Bahá'í sacred writings. Rather than rules there is an emphasis on guidance and on the responsibility of individual believers to live a virtuous life. Food rules and practices are often used as boundary markers in religions and as a way for believers to assert their faith identities. The absence of such prescriptive dietary codes in Bahá'í teachings exemplifies the Bahá'í concept of the unity of humankind by removing one boundary between races, cultures, and religions. There is no symbolic value attached to particular foods, nor are there foods that are associated with specific rituals or celebrations. Generally speaking Bahá'ís follow local dietary custom. Nevertheless, there are three aspects of food that are explicitly addressed in Bahá'í sacred writings: the relationship of diet to health, fasting, and commensality as exemplified in the Nineteen Day Feast.

### Role of Religion in Shaping Daily Diet

There is a special concern for the strength and well-being of the body as the temple of the human spirit. The body should be a willing, obedient, and efficient servant, kept in good health so that the Bahá'í can devote all his or her energy to serving Bahá'u'lláh's purpose. To this end, Bahá'ís are expected to take responsibility for looking after their own health, in which diet plays an essential role. Both asceticism and hedonism are to be avoided; the former because it is an inappropriate withdrawal from the world and a rejection of what God has provided, and the latter because one should not be preoccupied with material possessions. Instead, moderation is advised as a

means to achieve a state of “detachment” necessary to attain true understanding of God’s will.

The ideal regime is a balanced natural diet that is adapted to local climate and to the type of work in which the body is engaged. Although animal food is not forbidden, meat-eating is considered to be only a temporary necessity of the current age, one that will give way in the future to vegetarianism. Vegetarianism is portrayed as being a compassionate practice, for the killing of animals blunts the spiritual qualities of the human race. A meatless diet is also natural in that it uses simple foods that grow from the ground. Finally, vegetarianism is just; one should not eat lavishly while others starve.

Food is not only seen to be the chief way of maintaining health, but also the preferred means for treatment of disease. Health and disease are conceived of in terms of balance and bodily equilibrium reminiscent of Greek humoral theory and Ayurvedic conceptions of hot and cold. Disease arises from disturbances to the balance of the body, which can be restored through consumption of food containing the necessary elements to bring it back to health. Although a time is foreseen when improved medical knowledge and understanding will enable all illness to be treated by food, Bahá’ís are enjoined to take full advantage of the best that current medicine has to offer and to seek the services of competent physicians when they are ill.

### Fasting and Feasting

There is only one annual fast prescribed for Bahá’ís. The precepts of the fast are laid down in the *Kitab-I-Aqdas*, or Most Holy Book, of Bahá’u’lláh and along with obligatory prayer it is the most important of Bahá’í ritual obligations. The fast bears a marked resemblance to Islamic practice, the context in which it emerged. The Bahá’í fasting period lasts nineteen days from the second to the twentieth of March, and requires complete abstention from food and drink between the hours of sunrise and sunset. It is a period of meditation and prayer, a chance to renew one’s spiritual self, and a reminder of the need to abstain from selfish desires. The fast is binding on Bahá’ís in all countries but it is an individual obligation, not enforceable by Bahá’í administrative institutions. It applies to all believers from the age of maturity (thought of as age fifteen) until seventy, with exemptions for travelers under specified conditions; the sick; women who are menstruating, pregnant, or nursing; and those engaged in heavy labor, who are advised to be discrete and restrained in availing themselves of this exemption. Unlike in the Islamic model, fasters who are unable to meet their commitment do not have to offer any sort of restitution or make up the missed days later. Nor are sexual relations prohibited during fasting periods. Bahá’ís are allowed to fast at other times of the year but this is not encouraged, and is rarely done. Fasting itself is only acceptable if it is done purely out of love for God. This is reminiscent of the importance of *niyyah* or intent in the Islamic fast of Ramadan.

### SELECTION FROM *SOME ANSWERED QUESTIONS* BY ‘ABDU’L-BAHÁ

The science of medicine is still in a condition of infancy; it has not reached maturity. But when it has reached this point, cures will be performed by things which are not repulsive to the smell and taste of man—that is to say, by aliments, fruits and vegetables which are agreeable to the taste and have an agreeable smell. . . . All the elements that are combined in man exist also in vegetables; therefore, if one of the constituents which compose the body of man diminishes, and he partakes of foods in which there is much of that diminished constituent, then the equilibrium will be established, and a cure will be obtained (Sec. 73).

Feast has a particular meaning in the Bahá’í Faith, referring to the monthly community meeting known as the Nineteen-Day Feast. The original purpose of the Bahá’í feast was a means of creating fellowship, and is rooted in the Persian tradition of hospitality. Bahá’u’lláh enjoined believers to entertain nineteen people every nineteen days even if only water was provided. Over time the feast shifted from being a display of personal hospitality to becoming an institutional event. The modern Nineteen-Day Feast is held in each Bahá’í community on the first day of each Bahá’í month, and consists of three parts. The first is devotional and consists of readings from the Bahá’í sacred writings; the second is a consultative meeting where administrative and community issues are discussed; the third is a social gathering at which food is served. What is served is at the discretion of the host and is guided by personal preference and local custom. The Nineteen-Day Feast is intended only for the members of the Bahá’í community; however, non-Bahá’í visitors should be received hospitably at the social portion of the feast only.

The sharing of food is an important feature of Bahá’í social events. Food sharing also occurs through charitable activity and social action. However, where local community development projects supported by Bahá’ís involve food, these usually take the form of agricultural development rather than food distribution.

Paul Fieldhouse

**BAKING.** Baking refers to two culinary processes: cooking by dry heat in an enclosed oven and making up flour-based goods (breads, cakes, pastries) that are cooked by baking. By extension a baking day is devoted to making breads and cakes and includes the idea of a batch bake or tray bake made up in quantity for cutting into smaller pieces. Cooking flour-based items using a griddle is also considered a form of baking. “Roasting” meat or vegetables such as potatoes in the oven is also in practice baking. The idea is also implied in the clambake of shellfish, using layers of heated stones and seaweed.

Two trades are directly concerned with baking, the baker using yeast to make breads and the pastry cook producing delicate pastries and cakes. The demarcation is unclear in English, which often applies the word “baker” to someone who makes cakes. French distinguishes more sharply between the *boulangier* and the *pâtissier*, as does German between the *Backer* and the *Konditor*.

The technique has a wide geographical spread. It is used throughout North America and Europe, across the Middle East and North Africa, and into central Asia and northern India. The concept was introduced by Europeans to their former colonies, many of whom have continued the practice. Baking is exceptionally important in cultures that rely on wheat as their primary cereal. Methods and technology have developed principally to exploit and enhance the properties of the gluten it contains. Others (rye, barley, oats) contain less gluten but are used in northern and western European baking, usually as residual traditions from times when wheat was expensive and difficult to obtain. Maize does not lend itself to baking, although North American settlers managed to develop corn breads, and the Atlantic communities of northern Portugal and Spain also use it in breads and cakes.

The history of baking is one of interaction between ingredients, fuels, and oven technology. On a basic level virtually any food can be “baked” by burying it in hot ashes or placing it on a stone beside the fire, something that must have been known from the earliest times. Developing control to the point of producing items as diverse as breakfast rolls, soufflés, and chocolate brownies has taken thousands of years.

### Enclosed Ovens

Early advances included the development of enclosed ovens. One type was a pit oven in the ground with a fire in the bottom. These were known by about 3000 B.C.E. in Egypt, where they were hollow cones of clay that contained a layer of coals. The modern tandoor, a large ceramic oven sunk into the ground and fired with wood or charcoal, echoes this idea. Tandoors have limited applications for baking but are essential for breads such as the flat, leavened wheat nan of Persian and northern Indian traditions. The dough is slapped onto the clay sides of the tandoor and cooks fast. Tandoors become very hot, and the fire remains in the base throughout cooking. This

along with their shape makes them unsuitable for complex baking.

Another type was the beehive oven, a domed structure situated above ground. An early version is in an Egyptian tomb model of about 1900 B.C.E. Early ones were made of clay and had the advantage of enclosing food in a hot environment but allowing the baker the opportunity to make more than flat shapes. Stone or brick ovens of similar shape evolved later and can be seen at Pompeii. They were used for baking with wheat flour and sour dough leaven. Beehive ovens fired with wood became the primary means of baking in medieval and early modern Europe. They were used for wheat or rye breads and the sweet, enriched festive breads and cakes that developed from these breads.

To heat a beehive oven, a fire was lit inside. After a while the oven was cleaned out, leaving heat stored in the walls. This heat diminished slowly over time. It could not be controlled, but by the sixteenth century a sequence had evolved. Coarse breads were baked first, followed by white breads, pastries, and joints of meat (often in pastries or pies), and progressing to cakes that would burn at high temperatures. Residual heat was used for drying fruit or for confectioneries. It was a time-consuming and complex operation. The size of the ovens and scarcity of fuel led to the idea of baking communally. For a small charge customers could bake their own dough or meat in an oven owned by a village baker. Such habits were noted in southern England during the eighteenth century and were still observed in some Mediterranean countries, for instance Greece, in the early twenty-first century. Small clay ovens were also still used in some regions, such as the Iberian Peninsula.

Wood-fired ovens produce unique, much-liked textures and tastes. Italian restaurants sometimes use wood-fired pizza ovens, and French bakers advertise *cuit au feu de bois* (cooked with a wood fire). Baking in these ovens requires a peel, a special implement with a long handle and a flat plate at one end for lifting food into or out of these large and often extremely hot structures.

### Griddle Baking

Little is known about the history of griddle baking. An ancient and widespread technique, it was available to anyone with a fire and a flat stone. At some stage specially made griddles—heavy metal plates—developed. Although it does not use enclosed heat, its association with cooking flour-based items links it firmly to the idea of baking.

Griddle baking is associated with Scotland and Ireland, where locally dug peat is used for fuel. Peat gives a slow, gentle heat unsuited to oven baking. The tradition continued in South Wales where cheap coal was burned in open kitchen grates, over which the griddle was balanced. Typical products include Welsh cakes, like small biscuits, and Scottish griddle scones or drop scones, small

French print showing the interior of a nineteenth-century bakery. © GIANNI DAGLI ORTI/CORBIS.

thick pancakes. British crumpets and muffins (made from bread dough) are baked on modern versions of the griddle, gas or electrically heated hotplates.

Another item used for baking with a open fire was the Dutch oven, which could be regarded as a form of covered griddle. It consisted of a heavy iron pot with a lid, both of which were preheated before use. Food was placed inside the pot, the lid was put on, and hot coals were heaped over it. They were used for baking bread, biscuits, and cakes as well as for roasting meat and other cooking. Both griddles and Dutch ovens were easy to carry and were much used by North American pioneers. Baking with these implements was enhanced in the mid-nineteenth century by the development of bicarbonate of soda, leading to the development of Irish griddle-baked soda bread. Bicarbonate of soda and baking powder were promoted through recipe booklets and rapidly became popular for making biscuits, quick breads, and cakes in parts of Europe and North America.

Due to regional poverty and the availability of slow-burning fuel, the East retained a form of griddle baking. Chapatis, the thin flat breads of Pakistan and India, are baked on metal plates over fires of dried cow dung, a fuel that gives slow heat.

### Kitchen Ranges

Controllable heat was the key to modern baking. Initially this took the form of the cast-iron coal-fired kitchen range, an idea patented by Thomas Robinson, a London ironmonger, in 1780. Over the next century designs evolved to control the heat, partly through the work of the American statesman Count Rumford. Ranges became fixtures in many European and North American houses. For the first time convenient and controllable ovens existed, although they still needed skill for good results. However, gas was used as a fuel for domestic cooking by the 1880s, and electricity was introduced about a decade later, giving even more accuracy and ease. By this time numerous regional baked specialties had developed, including tortes and gâteaux in central Europe, Christmas *Lebkuchen* in Germany, and teatime cakes in Britain. North America inherited baking traditions from all European countries in the form of festive breads, cakes, and cookies. In turn, by the twenty-first century North Americans grew much of the wheat that sustained the baking traditions in their native countries.

### Utensils

Baking requires many utensils. Measuring is important, so most kitchens and all professional bakers possess

spoons, cups, and scales. Bowls are needed for mixing, sieves and sifters for flour or sugar, rolling pins for pastry, cutters and molds for cookies, and forcing bags and nozzles for soft mixtures. Paper is used to line trays and molds and to hold cake and muffin mixtures. Flat metal baking sheets are used to support anything from a round loaf without a pan to a batch of cookies.

Many loaves of bread are baked in oblong pans. Common cake pan shapes include square, round, and tube pans. Many cultures have special forms as well, such as the German *Rebrücken* (a ribbed half cylinder for baking a chocolate cake in a “saddle of venison” shape) and the Alpine and Rhine areas’ *Gugelbuck* (a tall, fluted tube pan). Novelty shapes run to Santa Claus and Easter lambs. Cake pans affect the rate at which mixtures heat, and ideally they should match the final volume of the cakes baked in them. Professional pastry cooks use many sizes, from the one-bite petit four up to cakes for large parties. Small shapes in special molded trays include patty pans for baking cupcakes or British mince pies and shell shapes for French madeleines. Pies and tarts, too, have special shapes, including plain round plates and tart rings with fluted edges. Cylindrical formers are used in England for raising pork pies.

In contrast, the only essential for baking meats or vegetables is a metal or earthenware container, although various patent “roasting tins,” intended to be self-basting for cooking joints of meat, were developed in the twentieth century. The use of a thermometer designed to show the internal temperature of a piece of cooking meat is often recommended by cookery books.

### Physanges

Despite the fact that it typically uses temperatures ranging from 300 to 500°F (150 to 260°C), baking is an inefficient method of heat transfer. It relies on a combination of radiant heat from the oven walls and air convection. What it does effectively is dehydrate the surface of food at a high temperature, producing delicious flavors and aromas. These are due to the Maillard reaction, in which amino acids contained in the food react with sugars during heating, producing the typical smells of baking bread and roasting meat.

Physically, three stages can be identified during the baking of bread. They were summarized by Harold McGee (1984) as, first, when the yeast cells have been killed by heat; second, when the maximum temperature has been reached inside the loaf, gelatinizing the starch and coagulating the protein; and third, when the Maillard reaction induces surface browning, producing the characteristic flavor. Cakes follow a similar basic pattern. Yeast is not involved, but the first stage includes the expansion of minute air cells in the mixture and the release of carbon dioxide from any chemical leavening present. In the second, flour, egg, and milk proteins coagulate, and starch gelatinizes as the batter sets into a solid foam. Browning reactions set in during the third.

Nutritionally, baking has little effect on cereal foods, although it reduces the thiamin (vitamin B<sub>1</sub>) content. Many baked items are energy-dense because of the quantities of starch, fat, and sugar they contain. Some keep better than others. French baguettes stale quickly, but English fruitcake keeps so well it can almost be regarded as a form of preserved food.

Baking meat has the effect of coagulating the proteins of which it is composed. They shorten and toughen, squeezing out some of the water they contain, leading to weight loss in the cooked item. Most cooks aim at a compromise when oven-baking meat. Muscle proteins coagulate at about 160°F (71°C) and after that become dry and tough. But connective tissue requires long cooking at high temperatures to convert it to tender gelatin. As with cereal foods, the thiamine content is reduced, and the Maillard reaction develops the flavor and aroma. While this has no nutritional effect, it is important in provoking appetite. Baking vegetables, a relatively slow way of cooking them, reduces their vitamin C content significantly.

**BALKAN COUNTRIES.** Countries on the Balkan Peninsula, a region in southeastern Europe, are bounded by the Adriatic and the Ionian seas in the west, the Mediterranean and the Aegean seas in the south, and the Sea of Marmara and the Black Sea in the east. The penin-

sula includes Slovenia, Croatia, Bosnia and Herzegovina, Yugoslavia, Macedonia, Bulgaria, Albania, Greece, and European Turkey.

The region was already settled in the Stone Age. The oldest people living there were the Thracians, the Illyrians, the Greeks, and the Celts. When the Romans invaded Illyria in 168–167 B.C.E., the area was politically and culturally united for the first time in history. The division of the Roman Empire into its Eastern and its Western parts in 375, and the split within the Christian church in 1054 furthered the gap between the peoples of the area (Eastern Orthodox, Catholic), influencing its political and cultural development.

Between the fourteenth and the end of the nineteenth centuries, a great part of the Balkan Peninsula was

united in the Ottoman Empire, influenced by its feudal system and civilization, which have strongly marked the culture of the Balkan countries even up to the present.

### Principal Characteristics of the Balkan Food Culture

The food culture of the Balkan Peninsula depended upon the historic, geographical, climatic, social, and religious elements. There are three main food culture areas: the Mediterranean, the continental lowland, and the continental mountain areas.

The Mediterranean area is divided into the coastal and the continental parts. People living along the coast tend their vineyards, grow olive trees, different kinds of vegetables, citrus fruits, spices, and they fish. Wine, olive

oil, cabbage, kale, different kinds of salad greens, cauliflower, figs, grapes, almonds, cherries, marascas, and different fishes are their main staples.

The continental part of the Mediterranean area has a well-developed agriculture. Farmers breed mostly sheep, goats, and poultry, to a lesser extent also cattle and pigs. Fields yield crops of wheat and corn, in some places also rice, cotton, sesame, and poppy. Fertile valleys are sprinkled with vineyards. Meals, therefore, consist mostly of meat dishes, but also of milk, milk products, and vegetables. Lakes provide freshwater fishes.

The continental lowland area, which is distinctly agricultural, starts north of the Balkan Mountains and Šarplanina. Vast fields of corn and wheat give plenty of food. Farmers grow oats, barley, rye, millet, and buckwheat. Since wheat is mostly sold for profit, dishes consist mainly of corn; corn bread is eaten in most places. Because of an abundance of corn, which is very important as fodder, cattle and pig farming are very developed; in the north, sheep and goats are bred as well. The meat of these animals plays a very important role in the food culture of the local population. Farmers also grow fruit, especially apple, pear, plum, and they cultivate walnut trees.

Sheep farming is important in the mountainous part of the Dinaric Alps and in the Rhodope Mountains; less important is cattle breeding. Meals generally consist of milk and different kinds of cheese, corn bread (*proja*), and polenta (*kaèamak*). Many dishes are prepared from cornmeal, eggs, and the *kajmak* cheese; one of these dishes is *èimbur*, boiled eggs covered with *kajmak*. Also popular

are vegetable dishes made from cabbage, beans, onions, green peppers, and eggplant. Vegetables pickled in vinegar (*turšija*) are consumed in winter. Meat dishes consist mostly of lamb and sheep meats, usually roasted or prepared in a number of different ways. Beef and pork, which are usually dried in the air and made into prosciutto, or smoked, are eaten during the winter months (*pastrma*).

### Individual Groups of Dishes

The food culture of the Balkan Peninsula displays Asian as well as west European influences. Even though the Oriental influence has been very strong in the last several centuries, ethnic characteristics and traditions have been preserved. Dishes consumed in this region therefore contain many similar elements, but may also greatly differ from each other. One of the characteristics shared by most is the use of numerous spices, onions, garlic, tomatoes, parsley, paprika, and capers.

Soups are prepared from vegetables, meat, herbs, or different kinds of fish. Meat soups usually contain a variety of vegetables, as well. Throughout the Balkans, spring is the time for a thick lamb soup (*mayiritsa*). Other popular vegetable soups are potato, leek, corn, or bean soups, or a soup made of zucchini with milk or eggs. Along the Danube River, fishermen prepare thick soups (*Alaska èorba*), while in coastal areas, they make soup from sea fishes (the Greek *khakhavia*).

In the past, meat did not play a central role in the food culture of the Balkans. It was, nevertheless, a highly esteemed food, which could be prepared in a variety of

ways. Grilling and spit roasting are characteristic of the Balkan region, and lambs, kids, or pigs are roasted on spits on prominent occasions, such as weddings and New Year's Day. People grill seasoned minced meat shaped in different forms (*ševapèiđi*, *pleskavica*), kabobs (*vešalica*, *šaiši kebasi*), lamb and veal cutlets, beefsteaks, or small pieces of meat with vegetables and mushrooms (*muđkalica*, *krzatmas*).

Also very popular are meatballs (*ćufte*), be it in or without a sauce, for instance, the *pasha* of Turkey or the Greek *kreftaidakiya*. Minced meat is also used for the preparation of meat pie (*burek*), which can also be filled with cheese or vegetables. Meat can be served in a stew (goulash, paprika). Chicken is roasted with an addition of spices and vegetables, such as olives, peppers, tomatoes, zucchini, and eggplant. Duck or goose is most often served roasted, sometimes with filling.

In Balkan cuisine, vegetables are often prepared as a main or side dish, usually consisting of legumes, cabbage, kale, root crops, zucchini, peppers, tomatoes, and eggplant. These vegetables are made into a ragout, or filled with rice, meat, corn, vegetable, or cheese, or stewed with rice and meat (*đuveđ*). Very popular dishes are those which are made from a mixture of vegetables, meat, and rice (*sarma*), or those prepared with vine leaves (*jalanđi dolmasi*), or other leaves (cabbage, kale, chard). There are different casseroles in which meat is prepared together with vegetables, for instance, the Albanian shepherd's pot, or the Bosnian pot. The Turkish moussaka, a baked dish consisting of layers of sautéed vegetables, meat, rice, or potatoes, is prepared throughout the Balkan Peninsula.

Oriental influence is most strongly felt in the great variety of pastries, which have always been an important part of festive meals in all Balkan countries. Among the most popular are different pastries drenched in sugar syrup, and strudels. Most of the sweets contain walnuts and almonds, which are also put into stuffed apples (*tufabije*), or fill walnut pies, cakes, and the famous baklava cakes made from paper-thin dough. Nuts are sprinkled on sweet noodles (*kadaif*). *Žito*, wheat with walnuts, is a festive dish from Serbia. On Christmas and Easter, which are among the most prominent holidays in the region, different kinds of cakes are still served; one of them is the *pinca* from the Croatian coastal area, or Greek *melomacaron*, and another is *kourabietes*. *Vasiljica* or *badnjađa* are prepared in Serbia and Bosnia. Tables filled with festive dishes display a great variety of the Balkan cuisine and a strong attachment to the traditional culinary tradition.

**BANANA AND PLANTAIN.** Bananas, including the dessert banana and the cooking types or plantains, are cultivated in more than 120 countries throughout the tropics and subtropics, according to the Food and Agriculture Organization of the United Nations (FAO) current statistics. In terms of total production the banana ranks after oranges, grapes, and apples, but when plantain production is added, it becomes the world's number one fruit crop. While commercial production of bananas is oriented to the fresh export trade destined mainly for temperate-zone markets, plantains and even unripe bananas—consumed boiled, fried, roasted, or even brewed—are a major staple food throughout the tropics.

The origin of the word "banana" probably derives from languages spoken in the coastal regions of Sierra Leone at the beginning of the sixteenth century. It is important to note that none of the major producing regions seem to have incorporated clear linguistic distinctions between dessert and cooking bananas in their languages. The Spanish word *plátano*—from which the English term "plantain" may have derived (Simmonds, p. 57)—does not have a precise origin but is employed throughout the Spanish-speaking world and its meaning changes with location: in most of Central and South America, while the word *banana* is used as in English, *plátano* is reserved for the plantain, whereas in Mexico and Spain—the latter including the Canary Islands, from which the banana is thought to have been carried to the New World (Galán Saúco, p. 9)—it is used for either bananas or plantains. The situation in Southeast Asia is somewhat different, where vernacular names do not differentiate between dessert and cooking bananas (*kluai* in Thailand, *pisang* in Malaysia and Indonesia, *saging* in the Philippines, *chiao* in China, or *choui* in Vietnam) (Valmayor et al., p. 13).

#### Taxonomy

According to Chesman, who in 1948 pioneered the modern classification of bananas (Simmonds, p. 53), most edible bananas and plantains belong to the *Eumusa* section of the genus *Musa* (family Musaceae) and derive from the species *Musa acuminata* Colla and *M. balbisiana* Colla, which correspond roughly to two species originally described by Linnaeus in his general botanical work *Systema Naturae* (1758) to which he gave the names *M. sapientum* and *M. paradisiaca*, the first referring to a plant producing horn-shaped fruit and similar to the modern "French

In nature all species, plants and animals, are diploids; that is, they have a chromosome number of  $2n$ , formed by the contribution of  $n$  chromosomes (genome) from each progenitor. For diverse reasons and by various natural genetic paths, plants with different levels of ploidy do appear sporadically (e.g.,  $n$  = haploids;  $3n$  = triploids;  $4n$  = tetraploids, etc.), and a side effect of this natural process is the loss of fertility. In the case of the banana, the appearance of triploids has proven beneficial to the consumer, as seedless fruits are produced.

Plantain,” and the second to a type similar to the most popular dessert banana of the tropics, the “Silk Fig.” Both of Linnaeus’s designations were soon widely applied, with any plantain being referred to as *M. sapientum* and all dessert types being referred to as *M. paradisiaca*. This outdated nomenclature is still used in some modern reference books and papers.

A completely different group evolved from the *Australimusa* section of the *Musa* genus, the so-called Fe’i bananas, common in the Pacific and composed of a group of cultivars characterized by the red sap of the plant and, chiefly, the fact that its fruit is produced in erect bunches rather than the hanging bunches typical of all *Eumusa* types. It is likely that several species, most particularly *M. maclayi* Muell., are involved in the origin of the Fe’i group.

In purely commercial terms, the most important dessert bananas are those of the Cavendish subgroup—sterile, seedless triploids (AAA) of *M. acuminata*, of which the best known cultivars are “Grande Naine” and “Dwarf Cavendish.” Others include AA diploids (such as “Pisang Mas” in Southeast Asia and “Bocadillo” in Latin America, both well known because of their excellent taste, which makes them highly prized by European gourmet fruit retailers), various AB diploids (*acuminata*  $\times$  *balbisiana*), AAA triploids (the best known is “Gros Michel,” at one time the world’s leading commercial cultivar but now virtually absent from cultivation because of its high susceptibility to Panama disease, a fungal wilt of serious economic importance), and AAB triploids such as “Silk Fig” (also known as “Pome” and “Manzano”), and the recently obtained AAAB tetraploid “Goldfinger.”

Cooking bananas are usually hybrids, mainly AAB or ABB triploids, with the exception of the so-called “Highlands bananas,” AAA triploids used in Africa mainly for beer production.

## Area of Origin and Main Historical Developmental Facts

Wild bananas were probably used in prehistoric times for, among other non-food purposes, cloth, shelter, and dyes. Interest in them as a food crop appeared early in agricultural history, doubtless linked to the appearance of parthenocarpy (i.e., development of fruit without pollination) and consequent lack of seeds in the primitive types of *M. acuminata* from which the modern edible triploids evolved. Many wild banana diploids and triploids are still abundant throughout southeastern Asia, with a primary area of origin in Malaysia and Papua New Guinea, while most of the plantains originated in India and the Philippines. In any event, both spread quickly to other tropical and subtropical regions of the world. The Fe’i bananas evolved throughout the Pacific islands from Indonesia to the Marquesas and still remain closely confined to the area.

The main recognized milestones of these movements are:

- c. 500 C.E. — Introduction to Africa from Indonesia (via Madagascar)
- c. 1000 C.E. — Distribution throughout Polynesia and introduction to Mediterranean areas during Muslim expansion
- 1300s–1400s — Introduction to the Canary Islands from West Africa
- 1516 — First recorded introduction to the New World (Santo Domingo) from the Canary Islands
- 1500s–1800s — Distribution of bananas and plantains throughout tropical America
- Early 1800s — Introduction to the New World from Southeast Asia of the cultivars Dwarf Cavendish and Gros Michel
- Late 1800s — Beginning of the international trade
- 1900s — Banana becomes a major food item in the temperate-zone markets of the Western world as well as in Asia

Many authors question some of these dates: particularly at issue is the well-documented distribution of the banana in South and Central America shortly after Columbus’s first trip, leading some historians to speculate on its presence in the New World prior to 1492. But until proof becomes available, the accepted explanation is that its rapid foothold and spread ran parallel to the slave trade, for which the banana was considered a staple food. The relative durability of banana propagation material and the rapidity with which the plant produces fruit favor this hypothesis, although the archaic uses of the plant’s materials still practiced today by some native communities of the Amazon basin, as well as the increasing body of knowledge pointing to the Asiatic ancestry of Native Americans—whose forebears could conceivably have brought banana seeds with them—also support the idea of an early introduction to Latin America (Moreira).

## Legends and Myths

The banana plant has been associated with the religions, folklore, traditions, and social customs of many cultures. In most cases these refer to the special botanical characteristics of the plant. A good example is the Indonesian myth “The banana and the rock,” which in short recounts how in the beginning, God gave humans a rock as a gift. Not at all pleased, the humans clamored for a different gift, whereupon God gave them a banana plant but with the caveat “You choose the banana and not the rock. Your life will be like this plant, in that soon after it has borne descendants the mother plant will die and the young shoots at its base will come into their own. If you had chosen the rock, your life would be eternal.” (Frazer, as cited in *Infomusa*, 1999). The banana is regarded in many cultures as a symbol of fertility and prosperity; thus, it is frequently planted in the corner of subsistence fields of rice, yam, and other basic crops to “protect” them. Throughout Southeast Asia and the Pacific the plant is an important part of the dowry, ensuring food for the newlyweds’ future family.

In New Caledonia the Fe’i banana, given its typical blood-red sap, is considered to be the reincarnation of ancestors, with different clones identified with the diverse clans and others considered privileges of the chiefs. The Yanomami tribe of the Brazilian Amazon use the fruit in their funeral rituals, eating a paste of ripe bananas to which the ashes of the deceased are added (<http://www.kah-bonn.de/ausstellungen/orinoko/texte.htm>).

In the East African highlands, the care and cooking of bananas are tasks reserved for women, with each elderly woman undertaking the responsibility to provide for ten men; beer bananas, on the other hand, are part of the male domain. In Tanzania, however, women prepare the beer and proceeds from sale are their only socially acceptable form of revenue. Hawaiian women, by contrast, were forbidden, under pain of death, from eating most kinds of bananas until the early 1800s (<http://hawaii-nation.org/canoe/maia.html>).

The Qur’an holds that the banana is the *Tree of Paradise*, and the notorious *forbidden fruit* that tempted Eve in the Garden of Eden could conceivably have been a banana rather than an apple, to say nothing of the leaf—certainly larger than that of the fig tree—with which she later covers her modesty. Simmonds provides some support for this, reminding us that Linnaeus did give the banana its scientific species name of *paradisiaca* (paradise), as well as that the frequent inclusion of “fig” in the common and cultivar names given to certain banana varieties cannot be purely coincidental.

Perhaps one of the best examples of the strong relationship between the banana and humans is the fact that in many languages the banana plant is referred to using terms that indicate people consider it as a family unit: “mother plant” referring to the plant while it is producing a bunch and that will become the “grandmother”

FIGURE 1

once that bunch has been cut; “son” or “daughter” plant referring to the sucker growing at the mother’s base, which will produce the next crop; the “parent crop,” referring to the plants that will provide the first harvest. In the same anthropomorphic line, the terms “hands” and “fingers” are assigned to the fruit (see Botanical Description).

## Botanical Description

Bananas and plantains are evergreen herbaceous tropical plants that can be considered giant herbs, as some varieties reach up to ten meters in height, although most commercial types grow to between two and five meters (see Fig. 1). The external “trunk” is in fact a *pseudostem* formed by the concentric assemblage of the leaf sheaths crowned by a rosette of large, oblong-to-elliptic-shaped leaves (ten to twenty under healthy conditions), conferring on the plant the aspect of a herbaceous tree. The *true stem* is a subterranean organ that extends upward at the core of the *pseudostem* until culminating in the inflorescence (the fruiting organ of the plant), which emerges from the top of the plant, and it is responsible for producing all the other parts of the plant: roots, leaves, and shoots or suckers. Leaves are produced successively until the inflorescence is cast, and in variable quantity depending on the specific variety of banana or plantain, climate, and cultural practices.

Although the plant dies after producing fruit, it can be considered perennial in as much as suckers successively replace the senescent aerial parts without need for

Banana ripening facility for Chiquita Brands International in Costa Rica. The bananas are ripened artificially and processed for export. COURTESY AP/WIDE WORLD PHOTOS.

replanting. Several suckers emerge consecutively from buds located at the axil of leaves; under commercial cultivation, they are regularly eliminated, leaving either the most vigorous sucker, or the one capable of producing a bunch when better prices can be obtained, to replace the mother plant.

The large and complex inflorescence is composed of double rows of flowers, called hands, and covered by bracts, usually red or reddish in color, grouped helixoidally along the inflorescence axis, reproducing the pattern of the leaf system. All flowers are hermaphroditic, but only the female or so-called “first” hands (in most cases between four and nine, but sometimes up to fifteen) will give rise to the edible fruit—technically known as fingers; the other hands are of an intermediate or even male character and do not produce edible fruit (these rudimentary fruitlets usually fall before the edible fingers mature). Commercial fruit develops parthenocarpically, although some varieties produce seed in the wild or can be forced to do so in specialized breeding work.

Depending mainly on climate, cultivation conditions, and varieties, the time lapse between emission of the inflorescence and harvesting of the bunch can be anywhere from three to ten months. Bananas are harvested year-round, with normal commercial bunch weights of 15–30 kg, although bunches of more than 45 kg are not unusual when properly cultivated (exceptional cases of bunches of

more than 125 kg have been recorded). A medium-sized dessert banana finger weighs around 160 g.

### Nutritional Value and Uses

Banana fruit is composed mainly of water (around 65 percent for banana and 75 percent for plantain) and carbohydrates (from 22 percent for banana and 32 percent for plantain). It contains several vitamins, including A, B, and C, and is very low in protein and fat but rich in minerals, particularly potassium (around 400 mg/100 g). It is cholesterol free, high in fiber, and low in sodium. Chemical composition varies not only among cultivars but also according to climatic and other conditions (values are widely available in most of the texts cited in the Bibliography).

Ripe fruit is usually consumed fresh—simply peeled and eaten as a snack or dessert, in salads mixed with other fruit, and with breakfast cereals, but it also lends itself to more elaborate dishes ranging from ice cream to pie fillings.

Plantains, being starchier than bananas, can be eaten ripe or unripe, but many countries have developed commercial processes to provide a wide variety of products from both fruits (in several cases, green bananas can also be used): puree, flour, jam, jelly, chips, crisps, flakes, dried, catsup, relishes or spreads, preserves, vinegar, and even wine. Banana flour, both from green and ripe fruit, has a great industrial potential and, enriched with sugar, powdered milk, minerals and vitamins, and artificial flavoring, is much used in baby foods. In several areas of Southeast Asia, young fruits are pickled. Puree is used in the manufacture of dairy products, such as yogurt and ice cream, in breads and cakes, banana-flavored drinks, baby food, and diverse sauces.

In Uganda—the country with the highest per-capita consumption of bananas and plantains in the world in 1996: 243 kg while people in most European countries only averaged between 7 and 15 kg—an important part of the diet comes from unripe plantains that are first peeled, then steamed wrapped in their own leaves, and finally pounded to a starchy paste called *matooke* that constitutes the main dish. Both Uganda and Tanzania produce and consume large quantities of beer brewed from local Highlands bananas. A plantain and soybean mixture, SOYAMUSA, combining carbohydrates and proteins, has been recently developed in Nigeria to be used as a weaning food for toddlers. All told, bananas and plantains represent more than 25 percent of the food energy requirements of Africa (Frison and Sharrock, p. 30).

*Tostones* is a very popular dish in the Caribbean: slices of green plantain are double-fried (flattening slices with a wooden press between fryings), producing a tasty side dish used in lieu of the ubiquitous french-fried potato. *Mofongo* is a typical Puerto Rican dish made from fried green plantain, pork, and garlic. Finely ground and roasted dried green plantain has been utilized as a coffee substitute in some countries (Morton, 1987, p. 43).

Although the fruit is the main economic product, many parts of the banana plant can be used as food, fodder, or for industrial purposes. Throughout the tropics, male buds, young flowers, and even the pseudostem of some cultivars are eaten cooked as vegetables. Flowers and ashes from burned green leaves and pseudostems are used in curries in Southeast Asia. The possibility of using the raquis to prepare a flour for human consumption and of making a marmalade from plantain peel is being studied in Colombia. Leaves are used for wrapping other food during steaming or other cooking, such as in preparing the Venezuelan *hallaca* and many pit-steamed or pit-roasted meats and vegetables typical among the Pacific Islanders. Banana leaves are also used as environmentally friendly “disposable plates” in southern India, where in fact several cultivars (mainly AAB or ABB plantain types) are grown exclusively for leaf production (Singh, p. 27).

Green and commercially rejected ripe bananas are currently used as animal feed. Leaves, pseudostems, bunch raquis, and peels are also commonly used in fodder. In the Canary Islands (Spain), fresh, chopped banana leaves make up about 80 percent of the diet of Pelibüey sheep.

### Medicinal and Therapeutical Value

The easy digestibility and nutritional content make ripe banana an excellent food, particularly suitable for young children and elderly people. In the green stage (and after liquefying) it is used in Brazil to treat dehydration in infants, as the tannins in the fruit tend to protect the lining of the intestinal tract against further loss of liquids. In general, the banana is appropriate for consumption when a low-fat, low-sodium, and/or cholesterol-free diet is required, making it particularly recommendable for people with cardiovascular and kidney problems, arthritis, gout, or gastrointestinal ulcers (Robinson, p. 216).

As the fruit is easy to carry and peel, it is of great value to athletes as a quick and healthy method of replenishing energy because of its high energy value: 75–115 kCal/100 mg of pulp (the lower range for banana and the higher for plantain). Both bananas and plantains contain complex carbohydrates capable of replacing glycogen and important vitamins, particularly B<sub>6</sub> and C, and minerals (potassium, calcium, magnesium, and iron). Ripe fruit has been used to treat asthma and bronchitis, and, as mentioned, in the control of diarrhea. Boiled and mashed ripe fruit, especially when mixed with other appropriate plants, is also cited as a good remedy against constipation.

The juice extracted from the male bud is thought to be good for stomach problems. The peel of ripe bananas has antiseptic properties and can be used to prepare a poultice for wounds or even applied directly to a wound in an emergency. The banana pseudostem is also cooked in India as a dish called “Khich Khach,” to be taken monthly to prevent constipation. Fresh leaves have reportedly been used medicinally for a whole range of dis-

orders from headaches to urinary tract infections—at one time, stem juice was considered a remedy for gonorrhea. Many of these purported remedies are not well documented and require further investigation.

### Modern History, Commercialization, and Trade

The greatest development of the international banana trade occurred in Latin America during the second half of the nineteenth century, with exports from the West Indies and Central America to markets in North America. It was linked inexorably to railway and port expansion and to land concession policies. The founding in 1899 of the United Fruit Company—of Chiquita brand renown—is generally considered to be the fundamental milestone in this process. According to several sources, over the course of many decades this company wielded considerable power over the governments of several Central American countries, to which it allegedly “contributed” around 30 percent of its net operating profit. Thus the term “banana republic” came into use to define a country whose government was manipulated, and presumably corrupted, by the economic clout of a private enterprise.

From harvesting to consumption, bananas require careful handling as the fruit is very susceptible to physical damage and needs proper (cool) storage to avoid quick ripening and decay. After the bunch arrives at the packing house, it is deheaded and broken into clusters of 4–6 fingers each. Both hands and clusters are washed, usually by passing through tanks containing disinfectant solutions, and packed in cardboard boxes holding 12–18 kg on average. Modern refrigerated ships, equipped with holds that feature controlled temperature and humidity, transport the boxed fruit from the producing countries to distant markets. Temperature during transport is extremely critical: between 13 and 14°C guarantees that fruit will reach its destination in optimum conditions, whereas a short exposure to 12°C or colder temperatures will damage the fruit beyond repair by deteriorating its taste.

According to export trade figures, the major supplying countries can be divided into three groups: 1) the Dollar area, including most Latin American countries (where the trade is largely in the hands of multinationals like Chiquita, Dole, or Del Monte); 2) the ACP area, named for the African-Caribbean-Pacific countries that were signatories of the 1975 Lomé Convention and later treaties with the European Union (EU) designed to protect their economy, largely based on agricultural products; and 3) European producers, particularly the Canary Islands (Spain), the French West Indies, and the Portuguese islands of Madeira.

The main importers are Japan (mostly served by the Philippines), the United States, and Canada (supplied almost exclusively by the Dollar area countries), and the European Union (shared among all the major supplying groups by virtue of the Common Market Organization’s

banana regulations, which broadly follow the World Trade Organization precepts regarding free trade while safeguarding the traditional economies of ACP countries and EU ultraperipheral regions). Organic production is of increasing importance to import markets and, as is happening with other products, its impact on world trade should be felt in the near future.

About 95 percent of the world export trade is based on Cavendish bananas, but plantains are also the subject of recent interest, especially in Europe because of the burgeoning immigrant population of chiefly African and Latin American origin. Other specialty or exotic bananas, particularly those with red peels and/or flesh, but also *apple* ("Manzano"), *baby banana* ("Bocadillo" or "Pisang Mas"), and *ice cream* ("Lady Finger") types are commercialized on a small scale to satisfy niche markets.

**BARBECUE.** While meat grilled over a charcoal or wood fire is common to many cultures around the world, American barbecue is distinguished from these other dishes because of the cuts of meat it traditionally involves, the cooking techniques it employs, and the definitive sauces and side dishes that accompany it. Barbecue is cooked slowly at temperatures ranging from about 175 to 300°F with more smoke than fire. The meat involved varies from region to region. Traditional barbecue most often is pork, beef, lamb, or goat. However, chicken is also a popular barbecue meat.

The word "barbecue" is generally thought to have evolved from the word "barbacoa," which first appeared in Gonzalo Fernández de Oviedo's 1526 book *De La Historia General y Natural de Las Indias*. He describes the technique of skewering meat on sticks and then roasting it over a pit dug in the ground. The writing of Bernardino de Sahaún, who accompanied Hernán Cortés in his conquests of Mexico, uses the word "barbacoa" in references to meats roasted under the ground. References to barbecue cooking technique are also found in the 1698 memoirs of Père Labat, a French priest who wrote about his travels in the West Indies.

Several countries have culinary traditions that, to greater or lesser extents, could be called barbecue. For example, in India, meats are often roasted over charcoal in tandoor, a clay oven. In Jamaica, pork and chicken are barbecued "jerk" style over a slow fire of wood from the all-spice tree. In Mexico, whole goats are often butter-

fied, skewered, and cooked over a slow fire. In South Africa, the word *braai* is used to refer to the metal or brick pit over which meat is grilled, or to the event at which such meat is served. In Cuba, pit-roasted pigs are the traditional Christmas Eve dinner. In Brazil, *churrasco* refers to the technique of cooking meat on skewers over open pits. That country's *churrascaria* restaurants are famous for their all-you-can eat style of service. American barbecue enthusiasts generally refer to the technique involved in cooking steaks, hamburgers, or fish over an open fire as "grilling" rather than "barbecueing."

The word "barbecue" can be employed as a verb when it refers to the cooking technique. It is also an adjective, as in the phrase "barbecued ribs." And it is a noun when it refers to the gathering at which barbecue is served, as in the sentence, "We are going to a barbecue." Barbecue is important in the American culinary lexicon for two main reasons. First, it takes place outdoors, the cooking is often a public if not a communal event, and it is closely associated with family gatherings and such holidays as Independence Day and Labor Day. Second, barbecue is closely associated with particular regions of the country. The cultural identity of those regions and the people who live in them are inextricable from the style of barbecue served there.

Several theories have been advanced about how roasted meat evolved into American barbecue. The writings of Thomas Jefferson and George Washington include references to barbecue. The event is clearly related to the pig roasts common in Great Britain. While pig roasts may have been common in New England, barbecue did not take root there. Rather, in the eastern United States barbecue is most closely associated with states in which enslaved Africans did much of the cooking. Many of these people were transported from Africa via the Caribbean islands, where they may have learned some of the barbecue techniques of Native Americans. Mexican-Americans continue to use the barbacoa technique described in the writings of Bernardino de Sahagún today.

Barbecue is primarily associated with the American South and is cooked and eaten by most of the region's ethnic groups. But the food was taken to other regions by African-Americans as they fled the South for factory work in the Midwest and other regions in the middle decades of the twentieth century. Barbecue ultimately became common in the area from Virginia over to Kansas, down to Texas, and across to Florida and in African-American enclaves in California.

Barbecue geography can be tricky in that often barbecue styles do not conform to the lines on maps. In the Carolinas, Georgia, and other parts of the Southeast, barbecue means pork, either whole hogs or pork shoulders, generally cooked over hickory or oak wood. It is then chopped, sliced, or pulled and served on buns. Sauces vary widely within the region. Parts of South Carolina are unique in that they use mustard as the basis of their

sauce. Parts of North Carolina and Kentucky are similarly unique in that they use a thin sauce that tastes like Worcestershire sauce. The most popular sauce throughout the Southeast is a thin vinegar-based recipe flecked with flakes of dried red pepper and sometimes sweetened with sugar. The most popular barbecue sauce in the country, a thicker, sweeter, tomato-based sauce, is also popular in parts of the Southeast.

Though coleslaw and hush puppies are common side dishes throughout the Southeast, the definitive side dishes are regional stews. In South Carolina and parts of eastern Georgia barbecue is often accompanied by rice and hash, a stew made with some combination of pork and pork organ meats. In Virginia, North Carolina, and Georgia, Brunswick stew is served. The ingredients in this dish vary considerably and can include wild game, corn, lima beans, potatoes, and tomatoes, depending on the locale. In Kentucky, where mutton is the preferred meat for barbecuing, burgoo, a stew similar to Brunswick stew, is the popular accompaniment.

In Tennessee the basic barbecue dish is pork served on a bun with mayonnaise coleslaw. There as in many parts of the barbecue belt significant differences exist between urban and rural barbecue. In urban areas the sauces tend to be thicker and sweeter, and barbecued ribs are a standard part of the menu.

The distinctions in Texas barbecue are based largely on proximity to Mexico. Barbacoa, cow's head cooked in underground pits with mesquite wood and served with salsa on tortillas, is a common Sunday morning meal. While beef brisket is the standard barbecue meat in most of Texas, people along the border often refer to this as "American barbecue" to distinguish it from barbacoa. In southern Texas pinto beans generally accompany barbecue, and the meat is usually seasoned with cumin and chili powder. Eastern Texas barbecue is primarily beef brisket, but baked beans are more common than pinto beans there. Potato salad often replaces coleslaw as a side dish in eastern Texas, and spicing of the meat is influenced less by Mexican flavors.

In Arkansas, Oklahoma, Kansas, and Missouri, where the southeastern and southwestern traditions merge, beef and pork are equally popular. The sauces in those places tend to be sweet, thick, ketchup-based recipes. In Chicago and other cities where African Americans settled, pork ribs are the staple rather than whole hogs or pork shoulders.

Unlike most home cooking, barbecue is generally cooked by men. Sociologists have several theories for this. Men may be attracted to the fact that barbecue is cooked outdoors and in public rather than in a closed kitchen. Also at the root of barbecue is a primitive technique, often involving chopping wood, taming a fire, and butchering large cuts of meat. These tasks are traditionally viewed as masculine, and the technique is passed down from father to son.

With an increasing emphasis on faster, simpler cooking, some commercial establishments have replaced wood and charcoal pits with electric or gas ovens. Additionally the popularity of barbecue sauce as a condiment has meant that sometimes any meat slathered in a sweet, ketchup-based sauce is improperly called barbecue.

**BARLEY.** Barley is recognized as one of the very first crops to be domesticated for human consumption. It remains one of the major cereal crops grown in the world: barley is grown on every continent on which crops are grown. It is well adapted to diverse environmental conditions and thus it is produced across a broader geographic distribution than most other cereals. Relative to other cereal crops, barley ranks fourth in total grain production. The grain of barley enters the human food chain via distinctly different routes. First, barley is used as an animal feed and therefore makes an essential contribution to the human diet indirectly through meat production. Second, barley serves as a substrate for the production of alcoholic beverages, in particular beer. Third, a minor amount of barley is used to produce a diverse range of foodstuffs eaten by humans.

#### The Biology of the Barley Plant

The scientific name of barley is *Hordeum vulgare* L. Barley is a flowering plant belonging to the family Poaceae (the grasses). In addition to barley, the grass family includes the crops most important to human existence, including rice, wheat, and maize, and other species such as sorghum, oats, rye, millet, and sugarcane. In European contexts, barley grain is often referred to as "corn." The genus *Hordeum* includes approximately thirty species that are indigenous to at least four continents. Barley is the only domesticated species to have emerged from the genus *Hordeum*, in contrast to other crop genera such as *Triticum* (the wheats) and *Phaseolus* (the dry beans), which each contain several domesticated species. The other members of the genus *Hordeum* exist as wild plants.

**Growth and development.** The life cycle of the barley plant first begins with seed germination underground. The first visible sign of germination is root emergence, followed by the emergence of the cylindrically shaped coleoptile, which is the first structure to appear above ground. Interestingly, most above-ground tissues of the barley plant initially develop from the crown, a structure located below ground. The first leaf grows upward within the cylinder of the coleoptile, and emerges above the soil. This and other leaves do not expand along their entire length; rather the outer section (the blade) does so, while the base (the sheath) remains formed in a hollow cylinder. New leaves emerge in succession up through the sheaths of the older leaves.

The barley plant is not restricted to the development of one main stem, as observed in maize. Rather, like most other small-grain cereals such as wheat and rice, barley produces several additional secondary stems termed tillers that emerge up from the crown beginning a few weeks after the emergence of the main stem. The number of tillers produced varies depending upon the barley genotype and the environment. For instance, under highly fertile conditions, plants will produce more tillers than if nutrient starved.

**Reproduction.** Barley varieties are classified as spring or winter types, depending on whether they need a cold treatment, ranging from two to several weeks before making the transition to the reproductive phase of growth. When barley switches to its reproductive phase, the true stems of some of the tillers, called culms, elongate upward. The flowering structure, known variously as the spike, ear, or head, is borne upward, ultimately emerging from the "boot," which is the sheath of the uppermost leaf on the culm (the flag leaf). The height of a barley plant when the spike has emerged varies greatly, but averages approximately eighty centimeters. The spike consists of a large number of individual flowers called florets, which are present in individual spikelets that are attached to a central stemlike structure called the rachis. Spikelets are attached in groups of three on opposite sides of the rachis. The total number of spikelets on a spike varies,

but averages approximately sixty. The awns are a notable feature of the spike. They are hairlike extensions that emerge upward from the lemma, one of two thin sheets of cells that surround the floret (the other is the palea). Awn length varies considerably among barley varieties.

Barley is also classified based upon the fertility of the florets on the spike. In six-rowed barleys, all of the florets are fertile, leading to six vertical rows of seeds on the spike. In contrast, in two-rowed types only the central floret of the three at each node is fertile, and thus just two rows of seeds develop on opposite sides of the rachis. The fertile florets consist of both male and female reproductive structures, and fertilization occurs as the spikes are emerging from the boot. Barley is thus predominantly self-pollinated. Between twenty-five and sixty seeds per spike are produced, and for spring barley the seed matures three to five months after planting.

**Characteristics of the barley grain.** Barley seeds are approximately eight millimeters in length and weigh approximately fifty milligrams when mature, though there is a considerable range in these values between varieties. In most cases, the harvested barley grain includes the seed, a small structure called the rachilla, and both the palea and lemma, all of which adhere firmly to the seed. Barley grain in which these structures remain attached is referred to as covered barley, with the palea and lemma, collectively termed the hull. However, barleys in which the palea and lemma do not adhere to the seed are also well known. These hullless barleys share harvesting features similar to wheat, because when harvested the seed is cleanly separated from all other components of the spike.

The barley seed consists of the embryo, a series of outer layers of cells called the pericarp, and the endosperm. The endosperm contains different nutrients that the embryo draws upon as it grows into a plant. The principal compound found in the endosperm is starch, which represents about two-thirds of the mass of the seed. This starch serves as an energy source for the seedling. Another significant carbohydrate, the  $\beta$ -glucans, are components of the endosperm cell walls. The second largest component of the barley endosperm is protein. The amount of protein present is generally inversely proportional to the amount of starch. This protein provides a source of amino acids that can be used for protein synthesis by the seedling. The amount of protein present in a seed is positively correlated with the amount of nitrogen fertilizer applied when the parent plant is being grown. Additionally, the barley grain contains a large variety of other compounds present in minor amounts, including mineral nutrients and different organic compounds, including various vitamins.

### The History of Barley Use

The progenitor of cultivated barley is *Hordeum vulgare* subspecies *spontaneum*, or wild barley. Wild barley is still

Barley spikes from two-rowed and six-rowed types. PHOTO COURTESY OF DAVID GARVIN, USDA-ARS.

widely distributed in a large geographic region ranging west from Israel, Turkey, Syria, and Egypt, eastward to Pakistan, India, and into western China. It is particularly prevalent in the Fertile Crescent region of the Near and Middle East. Biological evidence for wild barley as a progenitor of cultivated barley is suggested by the fact that they both have the same base chromosome number (seven), and can be easily crossed to produce fertile offspring. Wild barley is two-rowed, and thus the first domesticated barley was two-rowed. Six-rowed types and hullless barley emerged not long afterward from the domesticated two-rowed types, due to a few chance mutations. Several traits have been selected in barley compared

to wild barley, which facilitate harvest, storage, and utilization. The most important of these are nonshattering spikes where the seeds adhere to the rachis and allow easy harvesting, increased straw strength, larger seeds, and reduced grain dormancy.

Along with wheat, barley was one of the first crops to be domesticated by humans and thus it played an important role in the emergence of agriculture in the Old World. There is rich evidence of barley in the archaeological record from numerous sites throughout the Near and Middle East, supporting the notion that it was a common and important crop in ancient times. It is likely that barley was already domesticated and being cultivated as early as ten thousand years ago, though wild barley was likely being harvested as a food long before this. Further, early written records from various cultures bear frequent mention of barley, as does the Bible, reinforcing the fact that barley was an important crop. Indeed, barley remained an important human food crop for many millennia, but it was gradually supplanted by wheat. The rapid spread of agriculture from the Near East into Europe and Asia led to the broad dissemination of barley and its cultivation. In more recent history, barley was brought to the New World as far back as the explorations of Columbus. Barley was introduced to the eastern United States early in the seventeenth century, and the west coast of the Americas in the eighteenth century.

### Barley Production

Barley is grown on nearly sixty million hectares of land worldwide, resulting in the production of approximately 140 million metric tons of grain. The top ten barley producing countries include Russia, Germany, Canada, Ukraine, France, Australia, the United Kingdom, Turkey, United States, and Denmark. Barley producers select the appropriate varieties to be grown and crop management schemes to produce grain well suited to a particular end use. Specific producer considerations vary widely, but include the choice of variety to plant, the timing of planting and grain harvesting, and agricultural inputs such as fertilizers, herbicides, fungicides, and insecticides. In the Northern Hemisphere, in regions where winters are too severe to allow winter barleys to survive overwintering, spring barleys are planted, usually in April or May. In warmer regions where winter barleys can overwinter, planting is done in September or November.

Given that the producer obtains only a small profit margin for barley produced, additional agricultural inputs are minimized. For instance, nitrogen fertilization is managed to maximize yield without compromising end-use quality. Barley is also subject to damage by a range of diseases, including powdery mildew, stem and leaf rust, smuts, leaf blotches, viral diseases, and head blights. Thus these diseases are managed by a combination of strategies including the use of disease-resistant varieties, application of fungicides, tillage practices, timing of crop planting, and crop rotation.

When the barley crop is mature, harvesting is accomplished either by direct combining or by first swathing, which entails cutting the culms and allowing the grain to dry in the field, and then harvesting. Technology for harvesting ranges from a simple sickle in developing countries to sophisticated mechanical combines that cut the culms above the soil, move the harvested plants between rollers to dislodge seeds, and pass this over mesh screens, allowing the grain to fall into a collection bin and the chaff to blow back out to the ground. Once the grain is harvested, it may either be stored in bins on the farm, or delivered to a local grain elevator where it is purchased from the producer. The price paid for barley grain depends on its intended end use. After purchasing the grain, the elevator cleans, dries, and stores it, and ultimately resells the grain to the various businesses that use barley (feed, food, and malt industries).

### Barley Consumption

**Animal feed.** The principal use of barley grain is as feed for poultry, swine, sheep, and cattle. Worldwide, 60 percent or more of the barley that is produced is used for animal feed. The particular barley varieties used as animal feed are sometimes specially developed “feed barleys” with attributes such as high protein that are geared specifically toward this end use. Sheep can be fed whole barley; however, before barley is fed to other animals it is ground using a hammer mill or rolling mill, or may be flaked with steam-heated rollers. Thus, the final feed product may be whole, ground, flaked, or pelleted barley. Since the phosphorus in barley is generally more readily absorbed by animals than it is from other feed grains, the use of barley as animal feed tends to result in less potential environmental phosphorus contamination from the animal waste runoff. While barley grain is the principal part of the plant used as animal feed, in some instances barley plants themselves may be used as a forage hay for animals.

**Human consumption of barley.** Less than one-half of the barley produced throughout the world is used for the preparation and production of products directly consumed by humans. Only a minor amount of barley is actually used in the production of foods for human consumption, though the range of uses for barley within this context are diverse. In some regions of the world, barley is grown for human consumption where other grains do not grow well. When consumed as grain, hull-less barley is generally used because the absence of the hull makes the product more palatable and easier to process. Barley can be pearled, which removes the outer layers of the seed and the embryo, followed by processing to produce small rounded pieces of the endosperm. Covered barley can also be dehulled, milled, and polished to remove the bran layers, to produce a ricelike product. Pearled and polished barley are used in porridges and soups and as rice substitutes. Other food uses include barley flakes, flour for baking purposes (either alone or in

mixtures with wheat flour) to produce breads and crackers, grits, breakfast cereals, pilaf, noodles, and baby foods. Lastly, some barley is used for the production of distilled spirits such as whiskey, vodka, and gin, and for making vinegar and malted beverages.

***Beer: the main use of barley for human consumption.***

The truly unique feature of barley that sets it apart from other small-grain cereals such as wheat is that the vast majority of barley that humans consume is not in the form of solid food derivatives, but rather in the form of a single product, the alcoholic beverage beer. The production of beerlike alcoholic beverages dates back several thousand years, and beer may be the oldest fermented beverage consumed by humans. Many barley varieties are developed specifically to possess the chemical and biochemical properties desirable for this purpose; such barleys are called malting barleys. In contrast to feed barley, malting barley has a high starch content. Because of the greater value of the end product of malting barley compared to feed barley, malting barley brings the producer more money. However, barley must meet stringent specifications of the malting and brewing industries before it will be used for this purpose. Both two-rowed and six-rowed barley are used to make beer, with six-rowed types preferred in the United States and two-rowed varieties preferred elsewhere. Beer production is divided into two processes, barley malting and brewing, which are undertaken by independent industries.

***The beer-making process.*** Beer production requires just four ingredients: barley, water, hops, and yeast. Barley provides sugars and amino acids for yeast growth, and the yeast converts the sugars to ethyl alcohol in a process called fermentation. Before barley is used to make beer, it is converted to "malt" to render it a better substrate for brewing. Malting is essentially a process of truncated seed germination. When grain enters a malt house, it is first steeped in water for two to three days. After steeping, the barley is transferred to germination beds for three to four days. Here the grain begins to produce enzymes capable of degrading the starch, protein, and the cell walls of the endosperm, and degradation of protein and cell walls proceeds. The barley grains are then subjected to heat that kills the growing seedling and dries the remnant grain, but leaves intact the components of the endosperm as well as the enzymes capable of degrading them. The product that emerges is malt. Major malt producing countries include the United States, Germany, and France, while major importers of malt include Japan, Germany, and Brazil.

Malt is used by breweries for beer production. The malt is first milled and mixed with water in a process called mashing. This mash is allowed to rest at temperatures that encourage degradation of starch from the endosperm into sugars, by the enzymes present in the malt. The mash is then transferred to a container with a sieve on the bottom, called a lauter tun. Here the liquid frac-

tion of the mash, called wort, is separated from the residual solids by filtration. Traditionally, covered barley is used for beer production because the hulls of the barley malt settle in the lauter tun and participate in filtering out residual solids. The resultant wort contains the soluble components derived from the malt, such as sugars and amino acids liberated by enzyme action. Hop plant flowers (or a derivative of them) are added to the wort and boiled. The hop oils add certain bitter flavors to the beer and protect it from bacterial contamination. The wort is then cooled, transferred to a fermentation vessel, and inoculated with yeast. The yeast use the sugars and amino acids from the malt to grow, and as it grows the metabolism of the sugar maltose leads to the production of ethyl alcohol and carbon dioxide as by-products of the fermentation process. After fermentation, the yeast and other solids are allowed to settle out. This is followed by an aging period, carbonation, and final packaging to produce the finished beer. Thus, the role of barley grain in beer production is similar to its role in the barley life cycle: to provide nutrients for growth. However, in beer production the benefactor of the nutrients is the yeast and not the growing seedling.

Worldwide, well over one billion hectoliters of beer are produced annually, from approximately sixty million metric tons of barley. It takes approximately fifty grams of malt to produce a 375-milliliter bottle of beer, though this amount can be less depending on the type of beer and whether adjuncts (nonbarley sources of sugars, often rice or corn) are used. The largest beer producing countries include the United States, China, Germany, Brazil, Japan, the United Kingdom, and Mexico.

***Traditions.*** The principal barley product consumed by humans, beer is produced and drunk in large quantities worldwide. Beer is probably recognized as the beverage most strongly associated with celebration, relaxation, and social interaction, and has become a ubiquitous component of recreational activities. Beer is commonly consumed in a diverse range of settings, including the home, restaurants, and bars, and for a broad range of occasions, particularly social gatherings. For instance, beer is a fixture at professional sporting events of all kinds held around the world. The increasing demand for beer is reflected in the rapid expansion in the number of microbreweries, and in the growth in popularity of home brewing. Beer consumption continues to grow in popularity, with production doubling over the last thirty years to keep up with demand. In addition, barley plays a ceremonial role in some societies. For instance, in India barley is often used in marriage and other ceremonies.

**BEARD, JAMES.** Born in Portland, Oregon, Beard (1903–1985) spent most of his life in New York, spanning the continent as the father of American cooking and as the larger-than-life champion of American foods, reveling in their glorious abundance and variety. His father was a "Mississippi gambler type" who skipped town while his English mother, Mary Elizabeth Jones, an émigré to Portland, firmly ruled her son, her Gladstone Hotel, and the Chinese chefs in its kitchen. In his culinary memoir *Delights and Prejudices* (1969), Beard gives a fine account of growing up amid the backstairs comedy of the Glad-

stone, a drama which no doubt influenced his lifelong passion for the theater.

At nineteen he went to London to become an opera singer and then to New York to become an actor. To keep from starving, he opened a catering shop called *Hors d'Oeuvre* with friends in 1937 and three years later published his first cookbook, *Hors d'Oeuvres & Canapes*, followed by *Cook It Outdoors* in 1941. By combining food with showmanship, he channeled his theatrical energy into writing and single-handedly created the drama of American food. Over the next four decades—after a stint in the army and the United Seamen's Service, opening navy canteens—he would publish more than twenty books in addition to making extensive contributions to *House & Garden's* single-subject cookbook series and writing numerous articles for newspapers and magazines. With the publication of *The James Beard Cookbook* in 1959, he became America's leading food guru, preaching the gospel of honest American food to those who had earlier looked exclusively to Europe for guidance in all things culinary.

At six feet four inches, weighing 310 pounds at his heaviest, he was as large as his subject, and his persona

matched his message. He was among the first to promote both on television, when he appeared with Elsie the Cow for the Borden Company on NBC in 1946. He also initiated a new style of domestic cooking school to urge ordinary home cooks to take pleasure in their food. In 1955, he began the James Beard Cooking School in New York and soon added one in Seaside, Oregon. By teaching in all sorts of venues across the country, he created a network of devoted followers who continued to spread the word after his death.

That word was “fun.” During the postwar decades of affluence, he taught Americans, who had survived the Depression, World War II austerity, and native Puritanism, to have fun with cooking, eating, and living in the American way. His 1972 *American Cookery* defined and celebrated the tradition of American cooking he had inherited from a body of cookbooks that began before the Civil War with Mary Randolph and Eliza Leslie and stretched to his contemporaries Irma Rombauer and Helen Evans Brown. While his appetite for traveling was as large as his girth, and while he spent much time in France, he sieved the flavors of other countries through his own American palate to create a menu that was always exciting because of the new combinations it offered. While his meals and menus were eclectic, he would say that it was the cook, not a country or a culture, that unified a meal. His culinary library in the 12th Street townhouse he owned in Greenwich Village was vast, and he was instrumental in directing his cooking students toward the literature of cooking.

In 1986, his house became a living theater honoring his name and his mission as the headquarters for the James Beard Foundation, where chefs from around the world showcase their skills. Through events such as the

### ONION SANDWICHES

Brioche loaf or good white bread, sliced very thin  
White onions, peeled and sliced very thin  
Mayonnaise, preferably homemade  
Chopped parsley

Cut the brioche or bread into rounds with a biscuit cutter. Spread the rounds lightly with mayonnaise. Divide into two batches. Arrange a layer of onion slices on one batch and top with the other. Press together gently. Roll the edges in mayonnaise and then in the chopped parsley. Pile on a serving dish and refrigerate for several hours before serving.

—*Love and Kisses*, p. 364

“It has always been my contention that the people of the Western European countries ate pretty dull food until the discovery of America.”

“Like the theater, offering food and hospitality to people is a matter of showmanship, and no matter how simple the performance, unless you do it well, with love and originality, you have a flop on your hands.”

“The kitchen, reasonably enough, was the scene of my first gastronomic adventure. I was on all fours. I crawled into the vegetable bin, settled on a giant onion and ate it, skin and all. It must have marked me for life, for I have never ceased to love the hearty flavor of raw onions.”

Origins and Ancient History

From Late Egyptian Times to the Nineteenth Century

The Twentieth Century

Production and Social Use

#### ORIGINS AND ANCIENT HISTORY

##### The Origin of the “Cereal Wine”—Beer

The origin of beer lies far back in prehistory; there is evidence that it was being made at least eight thousand years ago in Mesopotamia, but it had probably been produced

for many thousands of years before, and perhaps in many different places. Its great success must be closely related to the development of cereal agriculture, which occurred about ten thousand years ago. The sequence of events might well have been:

1. Making a dough of grain (whether crushed or uncrushed), which then underwent spontaneous fermentation.
2. Baking dough into bread, soaking the bread in water, heating the result, and allowing it to cool and then to undergo spontaneous fermentation. (A similar process would have occurred if the grain had been mixed with water and boiled into porridge: after cooling, it would have undergone spontaneous fermentation.)
3. Steeping the grain induces sprouting and the synthesis of amylase enzymes that decompose the starch of the grain into sugar, a process that is aided by heated water and/or baking. After cooling in water, the spontaneous fermentation will start. Barley has the advantage of having a rather large excess of amylases in comparison with other cereals such as millets and sorghum.

When people learned to steep grain in water and then heat it slowly, the overall product was greatly improved. Another improvement to the process that was invented was to bake bread from crushed or malted grain and then immerse it in water and heat the result. If bread was the intended product, more crushed or malted grain could be added to the dough; if beer was desired, all that was needed was the addition of more water instead. It is unknown when the use of a starter (a small amount saved from a previous fermentation for use in the next fermentation) began.

All these primitive beers were, technically, ales (that is, top-fermented)—spontaneously fermented both by yeasts and by *Lactobacillus*, which gave the beverage a sour taste.

### Domestication of Barley, Wheat, and Rye

Domestication of the most important beer cereals—barley, wheat, and rye—started at least ten thousand years ago at the transition from the Pleistocene to the Holocene period in the Fertile Crescent, the region from the eastern Mediterranean Sea to the eastern part of the Tigris and Euphrates area. When the glacial ice finally started to withdraw in the Northern Hemisphere, the climate of the Fertile Crescent was mild, wet, and ideal for early man, and numerous species of wild cereal grasses (grains) available for gathering flourished. Subsequently, the climate got warmer and drier and agriculture, a more prolific and dependable source for grains and other foods, was developed through the domestication of wild plants. The exact course of this domestication is complex, and is based in part on climatic changes, plant availability, preadaptive technology, population pressure, and resource stress.

All three cereals, barley (*Hordeum*), wheat (*Triticum*), and rye (*Secale*) are grasses in the tribe *Triticeae*, and they have all in different varieties played a great role in the development of beer in the Eurasian region. In other parts of the world, other cereals have had the corresponding importance, for example, sorghum (*Sorghum bicolor*) in Africa, rice (*Oryza sativa*) in Asia, corn or maize (*Zea mays*) in America, and millets. Cereals not belonging to the wheat, barley, oats, maize, or rice genera are commonly referred to as millets and are found in America, Africa, India, and Eurasia.

All domesticated varieties of barley belong to the same species, *Hordeum vulgare*, and its wild form *H. vulgare spontaneum* crosses easily with all domesticated forms. The major morphological difference between the wild and the domesticated forms is a tough rachis (the main stem holding the seed clusters) in the latter. In principle, there are three forms of barley, the two-rowed, the six-rowed, and the naked-grain form.

In connection to beer, the most important domesticated wheat varieties have been einkorn (*Triticum monococcum*), emmer, and the bread wheat, *Triticum aestivum*. Einkorn is a diploid form close to its wild ancestor, emmer is tetraploid, and the bread wheat is hexaploid.

Domesticated rye, *Secale cereale*, is very closely related to wild rye, *Secale montanum*, which still grows in the mountains of Turkey, northwestern Iran, and the Caucasus. Wild rye is more cold- and drought-resistant than are wild wheat and barley. Cultivated rye is predominantly a winter crop and it can succeed under less favorable climatic and soil conditions than can wheat.

There was probably a close connection between the production of beer and bread, the domestication of bar-

ley, and the social and ceremonial importance of the alcohol in beer. Beer was produced from bread, and barley is a very suitable cereal for both bread and beer production. Additionally, alcohol has been emphasized to have an important role in social relationship, in matters of reciprocity and obligation. The archaeologists Solomon Katz and Mary Voight have proposed that the development of settled agriculture was dependent on the desire to brew beer.

### Mesopotamia

The oldest documentary evidence of beer brewing comes from Uruk in Mesopotamia and dates to about 3500 B.C.E.; it is found on clay tablets that tell the story of Gilgamesh in Sumerian, written in cuneiform with accompanying pictures. The tablets describe in great detail how beer was prepared, the different varieties of beer, how its brewing and selling was arranged, and how it was consumed. Röllig (1970) gives an excellent review of most of the details from the historic periods in Mesopotamia from the old Sumerian period (about 3000 B.C.E., which is the most interesting period for our present purposes) until about 1000 B.C.E.

At this time in Mesopotamia, barley was the most important cereal for both humans and animals. The grain was steeped into water and then either air- or oven-dried. After removal of the sprouts, the malt was milled. For brewing, various kinds of beer-breads or *bappir* were baked from unmalted barley or other cereals and added, along with sweeteners and spices; it has been proposed by some investigators that hops were sometimes used also. (The amount of emmer used was taken as indicative of the quality of the beer.) Then the malt and the beer-breads were probably mixed with water and heated, after which the vessel was removed from the oven to cool. It has been pointed out by Katz and Maytag (1991) that the “cooked mash” was spread out on mats to remove the spent grains and to allow the liquid to drain. By the time of the hymn to Ninkasi, from about 1800 B.C.E., a “filter” had become the symbol of the brewers. Consequently, long straws were not necessary any longer, and the beer could be consumed directly from cups. Before fermentation, spices, herbs, and sweet plant extractives with effects that were believed to be medicinal were added; the augmented sugars and microorganisms from the herbs helped to induce fermentation. (It is known that the brewers saved some of the wort from one fermentation to use it as a starter for the next brew, as has often been done in sour-bread fermentation.) Katz and Maytag (1991) also found in the hymn of Ninkasi that date juice and grapes or raisins were added to the wort to induce fermentation. The entire concoction was then transferred, with more water, into a fermentation vessel, which was long and narrow-necked to minimize the mixture of inside and outside air and decrease infection from outside. We do not know how long fermentation lasted, but probably most of the beer was quickly top-fermented into

weak ale, which was tapped from the bottom of the vessel through a filter after a few days.

In early Sumerian times, beer was drunk through long straws, with the remnants of all the ingredients still present in the beer; such a straw, made of gold, has been found in a tomb at Ur. In later times, the beer was filtered as described above and then drunk from small vessels.

Many different recipes and descriptions are preserved from the Mesopotamian period: “strong beer,” “red-brown beer,” “pressed beer,” “dark beer,” and “good dark beer,” for example. These beers were very heavy and thick—almost like syrup—and very nutritious. Although they were very strong and heavy, they could not stand long storage in the warm climate, and so the people had good reason to complain about sour beer. The goddess of beer of the Sumerians was Ninkasi, who was in charge of everything concerning beer, one of the most important ingredients of life in Mesopotamia, both as a food and socially. A Sumerian proverb says: “Who does not know beer, does not know what is good. Beer makes the home pleasant.” It is interesting to note that the first very important king of Babylonia, Hammurabi, who reigned between 1792 and 1750 B.C.E., issued a set of laws (known as the Code of Hammurabi) that governed civil and criminal matters, included in which are rules for making and serving beer. (One copy of the code can be viewed on a column made of green diorite that is housed at the Louvre Museum in Paris.)

### Egypt

For the ancient Egyptians also, beer was the preeminent beverage and was more popular than water, which often was contaminated; and although beer had a lower social status than wine, beer was a necessity for the household and the kitchen. Brewing was the woman’s task, as it was in Mesopotamia. The divinities presiding over it were goddesses and some kind of chief brewer (the official Kha-bau-Seker, who bore the title of “Controller of the Brewing Women”). According to Egyptian religious tradition, Osiris, the god of agriculture, taught the people to prepare beer. The Greeks connected Osiris with Dionysus, the wine god, who in turn was associated with the earlier Thracian god Sabazius. The connection between the Egyptian people, beer, and their gods—for instance, Hathor-Sekhmet—was very close. The intimate relation between baking and brewing in Egypt and in Mesopotamia is supported both by the use of the Sumero-Akkadian word *lahamu*, originally meaning “loaves” (compare Hebrew *laham*, “bread”), to indicate brewing and by the constant association of baking and brewing in Egyptian art. “Bread and beer” was the symbol of food and a greeting formula.

Artifacts dating from about five thousand years ago found in the ancient tombs of Beni Hassan in Egypt show an established practice of brewing, serving beer to the public, and exportation of beer through the city of Pelusium to many Mediterranean ports. *The Book of the Dead*,

Wooden figurine of a female brewer, ca. 2465–2323 B.C.E. This carving is located in the Egyptian Museum, Cairo. © GIANNI DAGLI ORTI/CORBIS.

which dates from the same era, depicts beer being made from barley and offerings of cakes and beer to various deities.

The process of malting and dehusking the malted grain is probably thousands of years old, and the methods of today are very similar. In general, the preparation of beer, as described in late Egyptian documents and in tomb art of all periods, did not materially differ from the methods of preparing present-day *bouza* or its African analogues; however, Egyptian beer was often flavored by such plants as skirret (*Sium sisarum*—a member of the water-parsnip genus).

The Egyptians used either malts of various grains (principally emmer), which were formed into dough, or dried bread, and yeast (*Saccaromyces winlocki*), which was fermented in a rather warm place. In principle, there were two methods:

1. Steeping the grain in water, and then aerating it, re-moistening it, grinding it, working it into a dough, and adding yeast. Finally, after fermentation, the whole mass was strained through a cloth or a sieve, and the filtrate recovered.
2. Drying bread, soaking it in water, and leaving it to ferment in a warm place, which is identical to the traditional method for making *kvas* (“kvass,” in English—a beer made in Russia, typically from rye).

The preparation of *bouza* in modern southern Egypt and the Sudan consists of the following steps:

1. Ground wheat, barley, or other cereal is kneaded with water and yeast.
2. After a short leavening, the dough is lightly baked into thick loaves.
3. Another fraction of wheat is moistened, exposed to air for some time, crushed, and then added to the previously prepared loaves after they have been crumbled.
4. The fermentation is initiated by adding some old *bouza*.

Flavorings are not added. The result is a thick beverage with a strong yeasty odor.

Beer was consumed primarily for pleasure and nutrition, but it was also used for cooking and for medicinal purposes, often as a constituent of mixtures. The beer given to the slaves was unfiltered and crude, but was very nutritious because it contained residual grain proteins and vitamins.

## FROM LATE EGYPTIAN TIMES TO THE NINETEENTH CENTURY

### Late Egyptian to Roman Times

The Egyptians exported beer to the Greeks, who traded it to Gaul, to Spain, and to the east coast of the Adriatic; it then spread to Germania (what is now Germany and some portions of central Europe), where it became very popular. Beer may also have been established in non-wine-producing areas at an earlier date. It is rather probable that beer production originated close to the geographic expansion of agriculture, which implies that beer could have been present in Europe at least around 3000 B.C.E., when use of the plow spread in Europe. In a female grave in Egtved in Denmark from about the year 1357 B.C.E. rests from an alcoholic beverage were found in a vessel made of birch bark. It contained rests of wheat, cranberry, honey, and bog myrtle (sweet gale). (Corresponding remains have been found in the Hallstatt beer amphora found at Kulmbach dated 800 B.C.E.).

In China, alcoholic beverages seem to have been present since 4000 B.C.E. in Dawenkou in Shandong; the oldest written documents come from the Shang dynasty, 1324–1066 B.C.E., written by Du Kang and describing the production of *jiu*. *Jiu* meant all alcoholic beverages, usually of 10–15 percent alcohol, obtained by fermentation of cereals, millet, and wheat. The process was first

to make a ferment cake, which provided molds and yeasts that then started the fermentation process in a mash of cooked cereals. During the T'ang dynasty, 618–907 C.E., the cereals for this process were either glutinous millet or glutinous rice. These processes later spread to Japan, Korea, and all of Southeast Asia. Prior to the introduction of this process in Japan, brewers saccharified the rice by chewing boiled and raw rice.

Beer was considered a barbaric drink by the Greeks and Romans, though, according to Pliny, beer was known in the Mediterranean countries before viticulture (the cultivation of grapes) became popular. There are frequent references—in Tacitus, for example—early in the common era to malt beverages being consumed by the tribes of Germania (as well as by the Saxons, Celts, Thracians, and Scythians), and even to the establishment of *tabernae*, or taverns. Originally, beer was produced from a variety of malted and unmalted grains such as millet, barley, wheat, oat, and rye, with different supplements such as honey, juniper, mushrooms, and bark—but without hops. In the Greek and Roman world, wine was the beverage of the upper classes and beer was the drink of the common people, as was the situation in pre-Ptolemaic Egypt. (For more details see Arnold [1911] and Hoffman [1956].)

### Medieval Times to the End of the Nineteenth Century

**Home brewing.** From the year 719, when the Lex Alemannorum (a code of laws formulated by the Franks) was promulgated, all people in the Germanic area were entitled to brew their own beer. Home brewing began in Great Britain in about the twelfth century. With the growth of towns, commercial operations started brewing and selling in the same establishment. Later, the point of sale was centrally located in a town or city. Growth of brewing was slow until the industrial revolution made large breweries possible.

The types of beer and brewing techniques of the Middle Ages survived until recent years in the Nordic countries, as has the old method of spontaneous lactic and alcoholic fermentation of *kvas* ("kvass," in English—a beer made typically from rye) in eastern Europe.

**Monasteries.** Monasteries have had an active role in the brewing and sale of beer, and in the improvement of brewing processes. Two of the first beer-brewing monasteries—with brewing activities dating back to the seventh to eighth centuries—were St. Gallen (in Switzerland) and Weißenstephan (in Bavaria), both of the Benedictine order. Beer was a substitute for wine, a good nutrient during Lent, and an excellent base for spices used medicinally. In the year 1000, forty of the houses of the monastery of St. Gallen were devoted to brewing; they produced strong beer, oat beer, and light beer for themselves, guests, and pilgrims, and for sale. In the early Middle Ages, there were four to five hundred monasteries brewing beer in Germany; the practice was international

and a large source of income for the monasteries. The famous Trappist beer is still made in Belgium by Trappist monks, whose order has developed from the Benedictine and Cistercian orders.

**Cities.** In southern Germany, Bavaria was a wine-drinking area until the Thirty Years' War (1618–1648), and the monasteries were the main producers of beer. During the twelfth and thirteenth centuries, cities were burgeoning and they created licenses to produce beer, which could be heavily taxed by the authorities. In the northern part of Germany, many competing breweries were developed and great volumes of beer were exported by members of the Hanseatic League to other parts of Europe. In the northern city of Hamburg, there were six hundred brewers in the sixteenth century, as contrasted with only thirty in the southern city of Munich in the fifteenth century. Some of the most famous breweries in the sixteenth century were in Erfurt, Einbeck, Zerbst, Naumburg, and Braunschweig.

After the Thirty Years' War, which destroyed the northern cities and Bavarian viticulture, most of the brewing shifted from the north to Bavaria, where by 1420 the monasteries had developed the method of bottom fermentation that produces lager beer. Before this development, all beers were top-fermented—that is, ales. In 1516 the *Reinheitsgebot* (Purity Law) was approved for Bavaria, which decreed that only barley malt, hops, and water were allowed for beer brewing. In 1551 another law was approved in Munich saying that bottom-fermenting yeast should be used. Northern Germany was opposed to the new law, and Baden and Württemberg did not accept it until 1896 and 1900, respectively. In 1906 it was accepted for lager throughout the German Empire. The only exception made was to allow wheat malt in the specialty ales *Alt*, *Kölsch*, and *Berliner Weisse* and in wheat beer.

**Grut and hops.** Ancient beer was flavored by many different spices, even medically active ones, during the centuries, and Hildegard von Bingen mentions in her *Physica*, which dates from about 1156, both hops and *grut* as additives to beer, which is the first documentation of the use of hops in beer. *Grut* was a mixture of several spices, chief among them being the leaves of bog myrtle or sweet gale (*Myrica gale*). It was used mainly during the thirteenth to fifteenth centuries and it survived in the northwestern part of Germany and in the Netherlands until the eighteenth century. In many areas, the authorities sold the right to use *grut* (*Grutrecht*). During these times, hops and *grut* were used for beer simultaneously.

Hops had been introduced for beer brewing sometime between the years 764 and 1156, when the first hop agriculture was found in Geisenfeld in the Allertau area in Bavaria, and when Hildegard wrote her *Physica*, respectively. The introduction of hops probably came via contacts of the Germans with Slavic peoples in central Europe. The acceptance of hops in beer was very slow and even forbidden in certain areas. By the year 1400,

the Dutch had already introduced hops, but it was not until the sixteenth century that the use of hops in beer was gradually accepted in England. One reason for this slow acceptance could have been the difference in taste of the beer, from a rather strong and sweet beer without hops to a less strong and somewhat bitter beer. The great advantage of hopped beer was the better storage capabilities it afforded.

**Ale and lager.** Ales were the only beer type in Europe before the advent of lager, beginning in the fifteenth century in Bavaria. In 1603 lager was forbidden by the city of Cologne. However, it slowly spread through Germany together with the Purity Law, and during the nineteenth century, production volume increased dramatically. The most important types of lager were the dark from Munich, the pale from Dortmund, and the pale and heavily hopped from Pilsen (pilsner). Dortmund Export became world-famous in the nineteenth century, and pilsner became the great winner in the world of the twentieth century. In the northern and western parts of Germany, ales dominated until the start of the twentieth century.

In England, Professor Charles Graham became interested in lager in 1888 and started a discussion about the two types of beer. It was not until the end of World War II that lager was accepted by the British people. One significant impediment to the success and spread of lagers was their great need for cooling.

In Britain, ales have been the popular beers and have influenced tastes in both British colonies and other countries through export. At the end of the seventeenth century, most of the export of ale from Britain went to America and the West Indies, but the trade of strong, sweet ale, "Russian Imperial Stout," and porter (a heavy, dark-brown ale) to Russia and the countries around the Baltic had begun. In the beginning of the nineteenth century, half of the ale exported by Britain went to Asia and Australia. That type was called Indian Pale Ale (IPA); it was strong, sweet, and highly hopped.

**Development in America.** Brewing in America started with the early British and Dutch settlers. As early as 1587, Sir Walter Raleigh malted maize (corn) for brewing, and hops were grown by 1637 in Charlestown, Massachusetts. Malt and ale were imported from Britain, and New York and Philadelphia became the main brewing centers in the eighteenth century. In Canada, brewing was initiated in 1620 by the monastery of Notre Dame des Anges. The first steam engine was installed in Philadelphia in 1819. At the beginning of the nineteenth century, there were 150 breweries in the United States, producing 160 thousand Imperial barrels (7.2 million U.S. gallons).

From 1840 onward, German immigrants began brewing lager, and the number of breweries increased to 4,131 in 1873; this number decreased to 1,092 in 1918 and 230 in 1961. In 1850, ale brewing was dominant, and in 1860, lager production was less than twenty-five percent of the total production of 3.8 million barrels. Hop

culture spread to California in 1851, Wisconsin in 1860, Washington State in 1866, and Oregon in 1880. After 1850, lager began to prevail, but brewing it required ice, and machines to make that ice. This requirement was met by the introduction of the refrigerator. The first one was installed in New Orleans in 1867.

**Brewing companies and the science of brewing.** By the beginning of the eighteenth century, three items had been invented that later had very great importance for the brewing industry: the hydrometer, the thermometer, and the steam engine. Both the hydrometer (along with its offshoot, the saccharometer) and the thermometer gave the brewer instruments to measure and monitor processes more exactly, and the steam engine—which replaced horses—opened possibilities of working with greater volumes in the brewery. All the vessels of the brewery were still of wood except the brew kettle, which was made of copper. The technical revolution during the eighteenth and nineteenth centuries, as well as the beginning of free trade among both cities and states, had a great impact on the development of the brewing industries in Europe and the United States, and it was during this time that most of the big brewing companies were started and formed.

However, the most important inventions for the breweries were made in the biological and biochemical fields. In 1833 Anselme Payen and Jean-François Persoz discovered an enzyme, diastase, that can split starch. In the late 1830s, Franz Schulze discovered the yeast cells, *Saccaromyces*; his discovery was confirmed by Louis Pasteur in 1857. The final synthesis explicating the fermentation process was performed by Eduard Buchner in 1897; he demonstrated that fermentation could proceed with just the juices of the yeast cells—without the living cells—showing that a complex of enzymes (zymase) is responsible for the conversion of carbohydrates to alcohol and carbon dioxide.

Before these discoveries, people did not know why and how fermentation occurred. Often they ascribed it to supernatural forces, and many used the same equipment from fermentation to fermentation; sometimes sourdough from bread baking was used to initiate the fermentation. In any case, most of these beers and ales were also lactic-fermented and thus sour. In 1883, E. C. Hansen from the Carlsberg Laboratories of Carlsberg Brewery in Copenhagen isolated the active yeast culture from bottom-fermentation yeast, which J. C. Jacobsen, the founder of the brewery, had brought there from Munich. This species was called *Saccaromyces carlsbergensis* (it was later renamed *Saccaromyces ovum*) and today is considered a variety of *Saccaromyces cerevisiae*, the common yeast organism. Jacobsen's method of isolation and pure-culture propagation of yeasts from single cells was rapidly adopted. By 1896 it was in wide use in lager breweries in many countries and has become the standard method.

Germany became unified during the nineteenth century, and it was then possible for breweries to sell their

products over a wider area than before. The first limited brewing company was formed in Dresden in 1838. Between 1831 and 1865, because of the great success of lager, there was a dramatic fall in the numbers of breweries producing ales in Prussia, from 16,000 to 7,400. The first scientific brewing research institutions were formed in Bavaria (Munich and Weihenstephan) in 1880, and in Berlin in 1883.

## THE TWENTIETH CENTURY

### Beer in 1900

The central area for modern beer development and beer culture is the portion of Europe from Austria in the south-east to the British Isles in the northwest. The Nordic nations are also beer countries, but, with the exception of Denmark, they have not played a significant role. At the beginning of the twentieth century, ales dominated the market in the United Kingdom, the northern and western part of Germany, and Belgium. Lager had started its spread from Bavaria to the big cities in Germany and to the neighboring countries. It had also become rather well established in the United States, but the populace of the United Kingdom had not yet accepted it.

### Beer Around the World

Around the world, Australia got Foster's beer, a lager, from the United States in 1888. East Africa received beer from the United Kingdom in 1922, and today, lager, ale, and sorghum beer are all brewed by African breweries. One of the best-known beers from that region is Tusker lager from Kenya. Guinness and Heineken also have large breweries in the area. In South Africa, lager is dominant. In 1904, China got its first lager, Tsingtao, and in 1916 the company was acquired by the Dai Nippon Beer Company in Japan. The Japanese then spread the beer-brewing culture to other parts of East Asia.

### Beer in the United States

The United States—where the brewing industry was well established before 1900, with a very wide production of different kinds of beers such as ales, stouts, and lagers—experienced a golden age of brewing between about 1870 and 1919. This, however, came to a halt on January 16, 1919, when the Eighteenth Amendment to the United States Constitution, which prohibited all alcoholic beverages, was ratified. Prohibition lasted from January 16, 1920, to December 5, 1933, when its repeal by the Twenty-first Amendment took effect. During this period, breweries had to survive on nonalcoholic products such as near beers, malted milk, ice cream, and so forth. Two of the surviving companies, Anheuser-Busch and Miller, ended up being two of the top three breweries of the

world. The top ten breweries produced about one-third of the world production of 1.25 billion hectoliters (hL, equivalent to 33 billion gallons) in 1995.

### World Production

During the twentieth century, world beer production increased from about 250 million hL (6.6 billion gallons) in 1900 to about 1.306 billion hL (34.5 billion gallons) in 1998, an increase of 522 percent. In 1900, production volumes in Germany and the United States were about equal and together constituted about half of the world production. In 1998, the United States produced 238 million hL (6.29 billion gallons) and Germany 112 million hL (2.96 billion gallons), which together represents only 27 percent of the world production. World production of beer was distributed by region in 1997 as follows: the Americas, 37%; Europe, 34%; the Far East, 23%; Africa, 4.5%; the South Pacific, 1.8%; and the Near East, 0.1%. The greatest increase in beer production is found in areas far away from the traditional beer countries—such as China, countries in Latin America, South Africa, and Turkey (an Islamic country). It is evident that they have evolved a new way of life. Two of the traditional beer countries, Germany and the United Kingdom, are still in the top ten in production, but they will probably soon be overtaken by some of the countries mentioned above.

### World Per Capita Consumption

Per capita consumption of beer in different countries shows which people have beer as their natural and central beverage. The top ten countries in 1999, each with a per annum consumption of at least 88.1 liters (23.3 gallons) per person, are still from the old beer center of Europe, which stretches from the British Isles to Austria and up to Denmark (Table 1)—except for Australia, which got its beer traditions from the British colonization of the continent. The newcomers are Turkey, some Latin

TABLE 1

6 Denmark	101.9	-6.1	32
7 U.K.	99.0	-3.9	31
8 Belgium	97.5 e	-26.4	43
9 Australia	91.2 e	-24.6	41
10 Slovakia	88.1 e	-16.0	39

SOURCE: *World Drink Trends 2000*, p. 15

American countries, South Africa, and several European countries (including some that have traditionally been considered “wine countries”). Except for the Czech Republic, the Republic of Ireland, and Austria, the traditional beer countries show a decrease in per capita consumption (Table 1).

### Lager and Ale

During the twentieth century, a variant of pale lager, pilsner, became the big winner all over the world—in Australia, the United States, and even the old ale area of the British Isles. Only northwestern Europe is bucking the trend: In Belgium, Trappist-Abbey and brown ales are increasing in production, as are *Altbier*, *Kölsch*, and wheat beer in Germany. In the British Isles, bitter ale, pale ale, mild ale, Scotch ale, sweet stout, and barley wine are decreasing in consumption; only bitter stout is increasing. Consumption of draft beer in Great Britain for 1999 is as follows: lager, 44.8 percent; ale, 42.2 percent; stout, 6.3 percent. The remaining 6.7 percent of the total consumption concerns packaged beer of all types. It was not until after World War II that lager truly began to succeed in Great Britain, and it took about fifty years for it to achieve approximately 50 percent of the British market.

### Beer Developments in the Twentieth Century

Characteristic of the development of beers and breweries during the twentieth century is the worldwide success of the American variant of the Bohemian lager, pilsner—crystal-clear pale-dry beer, often of the light type, with a low taste of malt and a low bitterness, frequently served very cold. Another trend is that the number of breweries has decreased, individual breweries have become bigger and bigger, and different companies have merged into great brewing conglomerates. In the United States, there were 750 brewing companies and plants in 1936; this number had decreased to 26 companies and 215 plants in 1989, despite a 440 percent increase in volume. Still another trend is the increase of popularity and consumption of beer in nontraditional beer-drinking areas such as Latin America, South Africa, and various parts of Asia. The exportation of beer is a huge worldwide business; Table 2 lists volumes for countries with large exports and imports.

The establishment of microbreweries, which started in 1981 and had increased to 500 breweries by 1992 in the United States, and has spread to other countries as well, is an interesting development that demonstrates the desire for high quality and diversity of beer. Other important developments are ice beer (made by freezing off some of the water); dry beer, with a very low content of residual sugar; light beer, with a low content of dextrins in the beer; low-alcohol beer (less than 1.5 percent alcohol by volume); and nonalcoholic beer (less than 0.5 percent alcohol by volume). Most important are the advances in biochemistry, which have allowed brewing to become

an industry based on science and technology. The industry has progressed to the use of stainless steel vessels and containers, and all processes are fully automated and all by-products are taken care of. The expenses for beer production are dominated by costs for packaging, sales, production, and taxes; only a very small proportion of the costs is needed for raw materials.

### Beer and Health

**Calories, vitamins, and minerals.** The effects on health of beer drinking depend to a large degree on which beer is consumed, how much, and by whom. Contents of alcohol, carbohydrates, and proteins differ greatly between low- and high-alcoholic beer. The nutritional value of heavy beer is significant, especially if the beer is unfiltered and contains yeast cells. The caloric value of beers varies from 276 kcal/L in alcohol-free beer, to 428 kcal/L in pilsner, to 660 kcal/L in a *Doppelbock* (double-strength bock beer—a heavy dark beer). For example, 360 ml (just over 12 fluid ounces) of ordinary beer with 419 kcal/L, 4.5% alcohol and 38 g/L carbohydrates will give about 5–12% of the Recommended Dietary Allowance (RDA) of folate, niacin, vitamin B<sub>6</sub> (pyridoxine), riboflavin, and pantothenic acid; 10.3% RDA of magnesium; and 13.5% RDA of phosphorus. Thiamine and pantothenic acid amounts are rather low in beer in relation to the caloric content. This implies that other dietary sources of B-complex vitamins are needed. Beer also contains some chromium, which is needed for glucose and lipid metabolism. The amount of chromium present can be significant for chromium-deficient people. Further, the low content of sodium tends to counteract the water retention seen in heavy drinkers, which, in fact, may typically result from their additional salty food intake. Aside from the caloric content of modern filtered beer, it cannot be

Menu in the shape of a Bierstein for Eitel's Old Heidelberg restaurant in Chicago, 1934. The restaurant served beer only from the Blatz brewery in Milwaukee, much like the pub and brewery arrangements in England. ROUGHWOOD COLLECTION.

regarded as an important nutrient, since the vitamin and mineral contents are relatively low, but it does make a contribution. To make a complete meal with beer, a source of protein and fiber-rich vegetables should accompany the beer.

**Medical effects of beer.** Although beer is a low-alcoholic beverage of less than 10% alcohol by volume (typically about 5 to 7 percent) in comparison with wine and spirits (about 10 to 50 percent), all the effects of alcohol must be considered. For reviews on this subject, see Cox and Huang (1991, 165–176) and Owades (2000, 19–26). Generally, beer has not been found to differ specifically in its physiological effects on a short- or long-term basis from other alcoholic beverages, if the effects are related to the

amount of alcohol consumed. Beer also has the advantage of filling the stomach more quickly than wine and spirits and will give a slower increase of blood alcohol level. Heavy drinking may provoke diarrhea or vomiting and cause excessive urination, all of which flush vitamins and minerals out of the body. Heavy drinkers of alcohol may get dilated cardiomyopathy with specific intracellular changes, which is a kind of congestive heart failure. In 1884, it was described as *Münchener Bierherz* (Munich beer-heart) by Bollinger. This type of disease also occurred during the period of addition of cobalt to beer to stabilize its head.

In the past, alcohol has, in the medical literature, usually been connected to negative and hazardous effects on the body; however, in recent decades, a large number of clinical studies have shown that moderate drinking (about two to three drinks or twenty-five to eighty grams [about 0.88 to 2.8 ounces] of alcohol per day) decreases the risk for cardiovascular morbidity and mortality in comparison with both a higher and a lower alcoholic consumption, and most studies indicate that there are no beneficial differences among alcoholic beverages (but see below). Subjective health has also been shown to be highest in persons with a moderate alcoholic consumption (100 to 199 grams [about 3.5 to 7.0 ounces] per week). The beneficial effects of alcohol might be explained by an increase of HDL-C (high-density lipoprotein-C), decreased levels of prothrombotic factors such as fibrinogen, and reduced platelet aggregability, vessel contractility, and pulmonary artery pressure in heart failure patients. Antioxidative compounds—which may decrease the oxidation of LDL (low-density lipoprotein) and the risk for atherosclerosis—such as polyphenols, gallic acid, rutin, epicatechin, and quercetin in red wine and in full-bodied and darker beers may have additional beneficial effects. The question of whether some alcoholic beverages have more prominent effects in these respects remains to be elucidated in further clinical studies. However, red wine has been proposed to be more efficient than other alcoholic beverages in a number of studies.

**Hops and medical effects.** Other effects of beer, such as the central nervous arousal and the sedative effects, can be explained by the general effects of alcohol. It has often been discussed whether compounds from hops might influence the physiological effects of beer. It is interesting to note that hops—dried, liquid extract, and tincture—are recommended by health-food specialists for various conditions: “Hops are stated to possess sedative, hypnotic, and topical bactericidal properties. Traditionally, they have been used for neuralgia, insomnia, excitability, priapism, mucous colitis, topically for crural ulcers, and specifically for restlessness associated with nervous tension headache and/or indigestion.” (Newall, Anderson, and Phillipson 1996, 162–163). Antibacterial activity toward gram-positive bacteria is documented, but the sedative effect needs to be documented, as most of the studies are made with hops in combination with other

herbs. Recurring suggestion has been made that hops and beer have estrogenic activity and that the infection of molds producing estrogenic mycotoxins is a significant problem. Recently, a potent phytoestrogen, 8-prenylnaringenin, has been identified in hops and shown to have a concentration in beer of about 100m/L, which is equivalent to a few mg/L estradiol or less. This concentration in beer is not considered to be detrimental, but handling and ingestion of hops might have estrogenic effects in humans. It is also possible that 8-prenylnaringenin might contribute to the health-beneficial effects of moderate beer consumption.

Sven-Olle R. Olsson

## PRODUCTION AND SOCIAL USE

Beer may be defined as a cereal wine: an alcohol-fermented (and sometimes concomitantly lactic-acid-fermented) beverage, produced from one or more malted cereals, such as barley, wheat, rye, oats, corn, or rice, or from mixtures of these and unmalted cereals. In the following, the product is called “beer” if barley is at least one of the main constituents of the malt; otherwise, it is called “wheat beer,” “rye beer,” “oat beer,” etc., as appropriate.

### The Basic Beer-Production Process

To ferment the starch inside the grains of the cereals, it is malted (softened by soaking in water and allowed to germinate) and mashed with warm water; this allows the diastases of the grains, which are activated by the malting and mashing processes, to break the starches into shorter carbohydrates, upon which yeasts can act. After separation, a clarified liquid, known as wort, is produced, which is then boiled with hops; this adds a note of bitterness to the beer’s flavor while killing microorganisms. After chilling, yeast is added (either naturally from the environment or as an intentional addition), and fermentation takes place. After clarifying and storage, the beer is ready for consumption.

### Classification of Beers

Beers can be categorized according to the type of cereal used, but it is more common to use the type of fermentation for this purpose: spontaneous fermentation, top fermentation, or bottom fermentation.

**Spontaneous fermentation.** Spontaneously fermented beers are produced without the active addition of any microorganisms to the wort. The microorganisms come from the surrounding air and the equipment used in the brewing process and are a mixture of yeast species and lactic-acid bacteria, a mixture that produces alcohols and lactic and other organic acids, and gives the product a sour taste. Examples are the Russian beverage kvass, which is typically made of rye, and Belgian Lambic beer and the old *Berliner Weisse*, which are both produced partly from wheat. All beers made before the introduction and knowledge of pure yeast cultures were in a sense made via spontaneous fermentation. However, most such beers (as well as wines) were made inside containers that were repeatedly used for this purpose. Such containers rapidly become infected with spores that continue to maintain the original species of yeast—that is, the ones that produced fermentation in the first place. The use of the same vessel and associated equipment from one batch to the next causes the cereal grains employed to continue to be cross-infected between brewings. Recent scientific studies indicate that these spores remain alive for decades, or even longer. Moreover, many beer-making traditions include the step of adding fruit, such as raisins, to the mixture; this practice assures that the yeasts that naturally reside on the surface of the fruit will become a significant part of the microorganisms that infect the mixture.

These types of beer are technically ales—that is, they are all top-fermented.

**Top fermentation: ales.** Top-fermented beers, ales, are fermented at a rather high temperature, about 64–72°F (18–22°C), letting the yeast float on the surface of the wort.

Typical ales are British and Irish pale ales, bitters, stouts, and porters; Belgian ales, such as Trappist and abbey beers; and western German ales, such as *Alt Bier* and *Kölsch*. The Bavarian wheat beers—*Weissbier* (*Weizenbier*)—are also top-fermented and are produced in different varieties: pale and dark, with and without yeasts remaining, and as bock and *Doppelbock*. Some of the British and Belgian ales can be very strong, up to about 12–17 percent alcohol by volume, while common ales have a concentration of 3.5–6.0 percent alcohol by volume. Ales were predominant before the great expansion in popularity of bottom-fermented beers, the lagers, in the nineteenth century.

It should be noted that the term “ale” has also been used to signify unhopped beer, as contrasted with hopped beer (Cantrell, p. 619).

**Bottom fermentation: lagers.** Bottom-fermented beers, lagers, originated in Bavaria, where a cold-adapted yeast strain had been developed over a period of many years in the cold caves used for fermentation and storage. A temperature of about 45–59°F (7–15°C) is typical for bottom fermentation. The cold fermentation and the location of the yeast cells at the bottom of the container yield better storage capabilities and a cleaner, more purely malty taste in lagers, in comparison with ales, which are usually more fruity and bloomy in flavor. The name “lager” implies it is stored in cold conditions. Lagers are the dominating beers of the world today: pilsner; Bavarian; Vienna; *Münchener*, pale and dark; *Dortmunder*; bock; and *Doppelbock* beers. The difference between them depends principally on the brewing liquid, the type of hops, and the type of malt used. Bock and *Doppelbock* beers have a higher alcoholic content, 6.0–7.0 percent by volume and 6.0–8.0 percent by volume, respectively, in comparison with the other lagers, 3.8–6.0 percent by volume. Bocks and *Doppelbocks* are spring beers; their high levels of alcohol were originally produced to compensate for Lenten fasting.

### Raw Materials

**Barley.** Barley is a grass of the genus *Hordeum* and of the family Gramineae; it is one of the most important cereals of the world, after wheat, maize (corn), and rice. Barley is mainly used for livestock feed and for beer malting. The world production for 1999 was 130 million tons, with the greatest producers being Germany (13.3 million tons) and Canada (13.2 million tons) (FAO, *Production Yearbook*, 1999). Barley is produced all over the world up to 70°N latitude; it prefers reliable rainfall, a long grow-

ing season, and deep rich soils, but it can stand much more difficult conditions. It is not as cold-resistant as wheat, and in some regions it is sown in the autumn (Kendall, pp. 109–111).

For malt production, the two-rowed form of barley is often preferred over the six-rowed, although both give excellent malts. The advantages of barley for malting are principally the following:

- The husk gives each individual grain of barley microbiological protection during malting, thereby helping to prevent the growth of mold.
- The husk provides a useful filter during traditional wort separation. The filtered material, spent grains (trub), is composed of husks, proteins, a little starch, and minerals. The trub is used for animal food (Narziss, 1995, p. 176).
- The gelatinization temperature of malt starch is lower than the inactivation temperature for  $\alpha$ -amylase, which is one of the main enzymes breaking down the starch into shorter carbohydrates. (Gelatinization accelerates the transformation to sugars and makes it more thoroughgoing.) (MacLeod, pp. 50–51)

For more detailed reviews see Hough, Briggs, and Stevens (1971) and Adamic (1977).

**Water.** The different composition of natural brewing water, or production water, from Pilsen, the Czech Republic; Burton upon Trent, England; Munich; Dortmund, Germany; and Vienna characterizes five types of different beers. Pilsen water has low concentrations of ions and is suitable for highly hopped lager beers with pale malt. Burton upon Trent water has high concentrations of calcium, bicarbonate, and particularly sulfate, and this combination has been shown to be perfect for highly hopped ales with dark malt. The waters from Munich, Dortmund, and Vienna have rather high concentrations of alkaline ions, and Dortmund water in particular has rather high concentrations of calcium and sulfate. Vienna water is more highly mineralized than Munich water, with a rather low sulfate but a higher bicarbonate concentration. The waters from Munich and Vienna give a lager that is not heavily hopped and is used with both light and dark malts. The *Dortmunder* lager is more highly hopped and has a slightly higher alcohol content and a pale malt.

Brewing water must be of potable-water quality. The ion composition and pH can be adjusted by ion exchanges, for example. The pH before wort boiling should be 5.4, so as to obtain a pH after boiling of 5.2 (Moll, pp. 138–139). The different ions of the brewing water have profound effects on the malting and brewing processes, the fermentation, the flavor, and, as a result, the type and quality of the beer. The previously mentioned famous beers are distinguished by the effects of geological conditions of their wells on the brewing water. The important cations are calcium, magnesium,

sodium, potassium, iron, manganese, and trace metals. The anions are carbonate, sulfate, chloride, nitrate and nitrite, phosphate, silicate, and fluoride. Their concentrations in the brewing water should comply with those found in water suitable for drinking (for standards, see Moll, pp. 134–135).

Some of the many effects of the ions are pH adjustments made by calcium, magnesium, carbonates, and sulfate from the brewing water and phosphate and organic acids from the malting. If calcium chloride is added, insoluble calcium carbonate, phosphate, and free hydrogen ions will form, which will decrease the pH. In contrast, pH can be increased when the brew is boiled, forming carbon dioxide from carbonate and hydrogen carbonate, which binds hydrogen ions. Many of the different anions such as carbonates, phosphates, and all the organic acids in the brew have buffering capacities (they minimize changes in the pH).

Besides these pH effects, many of the cations, including trace metals, work as coenzymes for many different enzyme systems. For example, magnesium is a cofactor in the metabolic enzymes necessary to produce alcohol and protect yeast cells by preventing increases in cell membrane permeability elicited by ethanol and temperature-induced stress. Other critical trace element cofactors are cobalt and chromium, which enhance the kinetics of alcohol fermentation.

Calcium, along with phosphates, provides thermal protection for mash enzymes and is the principal factor for pH adjustments during wort boiling. It also tends to inhibit color formation during the boil, and facilitates protein coagulation, oxalate sedimentation, yeast flocculation, and beer clarification. Magnesium works similarly to calcium and causes harsh bitterness (Fix, p. 5). Sodium, together with chloride, causes a salty taste in higher concentrations (>400 mg/l), but in lower concentrations it can be used to increase the “mouthfullness.” Sodium is also very important for sodium/potassium transport across cell membranes. The amount of potassium should not be excessive as it inhibits many enzymes in the wort preparation. Iron should be avoided as it inhibits the malting, gives color to the wort, decreases the “mouthfullness,” and causes a bitter taste. Iron is essential for the oxidative processes of the yeasts, especially terminal oxidation. Manganese works as a coenzyme in many enzyme systems and stimulates cell division and protein generation.

Sulfate, with calcium and magnesium, decreases the pH and stimulates the carboxyl and amino peptidases. The sulfate concentration in the brewing water determines the concentration of sulfate in the final beer (malt and hops also contribute to the amount of sulfate) but does not increase the amount of sulfur dioxide. Sulfate also increases the flower flavor of hops and gives beer a dry, bitter taste. Chloride stimulates  $\alpha$ -amylases and gives a soft and full beer taste as calcium chloride. Often, the

chloride/sulfate concentration ratio is used to describe the ratio of body and fullness in relation to dryness.

Nitrates and nitrites are the last stage in the oxidation of organic material and give beer a bad taste. Nitrites are toxic for the yeast cells. Phosphate ions in the brewing water are not acceptable because they indicate organic contamination. Silicates of calcium and magnesium have negative effects on the proteins and cause protein-unstable beers. Fluorides have no negative effects on the fermentation but cause the beer to become a little darker and have a broader taste (Narziss, 1992, pp. 17–52). For more details about the effects of the ions in brewing water, see Narziss, 1992; MacLeod; and Moll.

**Hops.** The cultivated hop plant, *Humulus lupulus*, with its relatives *H. japonicus* and *H. yunnanensis*, belongs, along with species of the genus *Cannabis* (e.g., *C. sativa*, hemp), to the family Cannabinaceae. Together with the nettle family, Urticaceae, they form the order Urticales. Hops are dioecious (i.e., there are individual male and female plants) and perennial and are indigenous throughout much of the Northern Hemisphere between 35° and 70° N, though mostly cultivated today between 43° and 54° N, and 37° and 43° S. The most important regions for hop cultivation are in South Africa, Australia, Argentina, the United States, Germany, the Czech Republic, and England, having an amount of daylight during the growing season of 15:27–18:42 hours, a mean temperature of about 50–66°F (10–19°C), and average rainfall of between 2.5 and 22.4 inches during the period of April to September in the Northern Hemisphere and October to March in the Southern Hemisphere (Barth, Klinke, and Schmidt, p. 49). The world production in 1999 was about 98,000 tons, with Germany contributing about 28,000 tons, the United States about 29,000 tons, and China about 15,000 tons (FAO, *Production Yearbook*, 1999). Many different varieties of hops with different contents of humulone (an antibiotic) and hop oils have been developed, particularly in Germany, England, and the Czech Republic. (For more details about the varieties, the history, and the trade, see Barth, Klinke, and Schmidt, pp. 1–383.)

Both pollinated and unpollinated cones (strobili) from the female plants are used, with the unpollinated ones used in Germany thought by some to yield a better taste than the seed (MacLeod, p. 80). Inside the infolded bases of the bracteoles (the small leaves from which the flowers grow) and on the seed are the resin-producing lupulin glands, which contain the essential compounds for use in beer: the resins humulone (the  $\alpha$ -acids) and lupulone (the  $\beta$ -acids), and the aromatic hop oils. The  $\alpha$ -acids yield, after boiling and isomerization, iso- $\alpha$ -acids, which contribute bitterness to the beer, and hop oils, which contribute to the aroma. In addition, hops also benefit beer by improving clarity and foam stability, and, most important, flavor stability because of bacteriostatic activity of the iso- $\alpha$ -acids (flavonoids) (Grant, pp. 157–167). Hops are the major preservative of beer.

**Other herbs and spices.** Down through history many types of herbs and spices have been added to beer (von Hofsten, pp. 208–221; Rättsch, pp. 28–40), and many of them have been considered to be remedies. Besides hops, sweet gale (*Myrica gale*) and marsh tea (*Ledum palustre*), two of the constituents of the old European mixture of beer additives, *grut*, are believed to have been in widespread use. Placotomus mentions in his book from 1543 the use of more than twenty plants as additives for beer (von Hofsten, p. 212).

Since 1516, when the *Reinheitgebot* (Purity Law) was approved in Bavaria, the use of additives other than hops in beer has been prohibited there; this inhibited the use of new herbs and spices, and new combinations of old ones, in beer in Bavaria. However, in Belgium and its surrounding areas, and in Great Britain, other types of beers using wheat and herbs and spices were developed. Many of the recipes are secret, but we know of the use of coriander leaves and seeds, cardamom, camomile, clover, grains of paradise (the seeds of the West African plant *Aframomum melegueta*), cinnamon, plums, peaches, cherries, coffee, chilies, and chocolate (Jackson, 1998, pp. 16–17).

**Yeast.** The living microorganism producing beer from wort by anaerobic degradation of sugars to alcohol is a yeast species, *Saccaromyces cerevisiae*, which is also used for baking and wine fermentation. The species has at least a thousand different strains (Barnett, Payne, and Yarrow, pp. 595–597). Two of them are *S. cerevisiae cerevisiae* used for top-fermentation of ales and *S. cerevisiae uvarum* (*carlsbergensis*) used for bottom-fermentation of lagers. They differ from each other by the temperature used: as noted above, 64–72°F (18–22°C) for the ales and about 45–59°F (7–15°C) for the lagers. Further, *S. c. uvarum* (*carlsbergensis*) has the ability to ferment the disaccharide melibiose, which *S. c. cerevisiae* is unable to do, due to lack of the enzyme melibiase ( $\alpha$ -galactosidase) (Russel, pp. 169–170). Different breweries have developed their own strains or mixtures of strains of yeast to maintain the distinctive qualities of their beers. Important requirements for a good brewing yeast are flocculating power (i.e., the capability of forming loose, fluffy clumps), ability to ferment maltotriose (a complex sugar found in the wort), head-forming potential, fermentation efficacy, interaction with isohumulones (forms of the antibiotic  $\alpha$ -acids produced by hops), response to fining (clarifying and purifying), and propensity for producing important individual flavor components (MacLeod, p. 84). In the San Francisco beer Anchor Steam, lager yeast is used for fermentation at a high ale-fermentation temperature, which gives a very interesting beer with the roundness and cleanness of a lager and the fruitiness and some of the complexity of an ale.

### Outline of Modern Brewing Procedures

Detailed descriptions of this highly technological and scientifically based process can be found in de Clerck (1957–1958); MacLeod (1977); Hardwick (*Handbook of Brewing*,

Hop-sampling warehouse at the Guinness brewery, Dublin, Ireland, circa 1915. To maintain the quality of hops used in brewing, samples were taken from various lots of newly purchased hops and tested. ROUGHWOOD COLLECTION.

1995); Hough, Briggs, Stevens, and Young (1982); Narziss (1992–1999); and Narziss (1995).

An outline of the different procedures is given by Hardwick (“An Overview of Beer Making,” 1995, p. 88).

### Beer Chemistry

**Malting.** The process of malting grain starts with steeping it in water. After several hours, the embryo begins to take up water and to grow. To produce energy, the growth hormone gibberellin acid is formed and transported to the aleurone cells around the starch-rich endosperm to start the formation of hydrolytic enzymes such as  $\alpha$ -amylase, endo- $\beta$ -glucanase, and peptidase. The cell walls of the endosperm contain  $\beta$ -linked glucan and pentosan, which are degraded by the endo- $\beta$ -glucanase and pentosanases. The net action is to solubilize and break down the cell walls and the small starch granules in the endosperm. The peptidases break down the peptides into amino acids, which are essential for yeast nutrition; the large polypeptides, which have not been used by the yeast cells during fermentation, are important for foam stability in the final beer, but in conjunction with polyphenols have the potential to form undesirable haze in the beer.

When the malting is completed, the malt has to be kiln-dried to stop the enzymatic activities and to reduce the water content so as to allow storage of the finished malt. The kilning is divided into two steps: the drying, at temperatures up to 176°F (80°C), giving a moisture content of 4 percent; and the curing process, at higher temperatures, yielding flavor components through the Maillard reaction. This reaction browns the malt, producing amino acid-carbonyl compounds, which undergo further transformations to yield the colored, aromatic compounds known as melanoidins. The higher the temperature, the darker the malt will be and the more the enzymes will be inhibited (Kendall, pp. 117–118; Fix, pp. 41–45). These compounds contribute both to dark color and to different varieties of burnt-sugar or caramel taste. The malt type and the mixture of malts forms the body or the “mouthfullness” of the beer and produces the basis of classification into pale, medium, and dark beers. If the malt is kilned over an open fire, it will acquire a definite smoky taste like the Bavarian *Rauchbier*, “smoke beer.” The feeling of “mouthfullness” can be decreased by splitting the residual sugar of the beer, the  $\alpha$ -glucans, dextrins, by exogenous enzymes during the malting process. The resulting carbohydrates will finally be fermented by the yeast. The process is used to produce diet, lite, light, and dry beers.

**Mashing.** The type of brewing liquid used for beer production plays a very great role. However, with modern technology, any type of liquid with the optimal concentrations of the different ions can be created from any water. Calcium ions contribute to a more acid mash by precipitating as calcium phosphate and thus setting hydrogen ions free from phosphate ions. The pH obtained in this way, 5.4, is favorable for the activities of amylases. Bicarbonate ions act in the opposite way and give a more alkaline mash, which is unfavorable, and thus they should typically be removed. Calcium sulfate is often added to the mash to decrease the pH and to give bitterness to ale. Nitrates and iron ions have deleterious effects on yeasts. For detailed discussions on brewing liquids and salts, see Moll (pp. 133–156).

Germany complies with the *Reinheitsgebot*, the Purity Law, which, except for *Weissbier*, permits only barley malt, hops, and water for beer brewing. In most other countries, however, adjuncts up to 50 percent by volume are added to the mash to decrease the cost and to balance the taste of the beer. The adjuncts can be sugar solutions, other malts, or other unmalted cereals, such as rice, maize, wheat, or barley (though both rice and maize must be precooked before their incorporation into the mash, as their starches have high gelatinization points) (Stewart, pp. 121–132).

The mashing can be performed by either infusion or decoction. Infusion mashing is performed in a single vessel at a uniform temperature of about 150°F (65°C), and after the mashing, filtration is performed in the same vessel. The decoction system starts with a low temperature, which is then raised by the removal, boiling, and return of a part of the mash. The whole mash finally is transferred to a separate vessel, the lauter tun, for filtration. In Britain, the infusion is used with well-modified and coarsely ground malt, whereas in continental Europe the larger decoction method is used with a finer grind and less well-modified malt. Decoction mashing is a more versatile procedure for different malts and also has the advantage of low temperature, which helps to maintain the stability of such heat-labile enzymes as proteinases,  $\beta$ -glucanases, and  $\beta$ -amylase (MacLeod, pp. 59–73; Narziss, 1999; Rehberger and Luther, pp. 247–322).

The objective of the mashing is to produce fermentable sugars from the degradation of solubilized starch, amylose, and amylopectin. The sugars obtained are glucose, maltose, maltotriose, maltotetraose, and higher dextrans to a total of about 70 to 75 percent, with the higher values coming from decoction malting. Unfermentable dextrans persist to the finished beer and are an important part of the mouth-filling experience of the beer. Proteins, peptides, and amino acids, as well as vitamins, inorganic ions, fatty acids, organic acids, tannins, and lipids, are extracted during the mashing and all are important for yeast fermentation.

The amount of malt used is directly proportional to the alcoholic concentration of the finished beer. About

one-fourth to one-third of the weight of the malt is metabolized to alcohol.

**Wort boiling.** The filtered sweet wort from the mashing is transferred to the wort vessel for boiling, which inactivates the enzymes, sterilizes the wort, lowers the pH via precipitation of calcium phosphate and removal of carbon dioxide from bicarbonate, concentrates the wort, denatures and precipitates proteins, dissolves any additional sugars used, isomerizes hop  $\alpha$ -acids, and removes unwanted flavor components. A long boiling process increases the shelf life of beer. Elimination of high-molecular-weight material (i.e., flocculation of the proteins) is increased by stirring and adding carrageen, a colloid typically extracted from the red alga *Chondrus crispus*. It has also been shown that the malty full-bodied flavor of beer declines and sharper notes are enhanced with rising temperature of heat treatment. The color of the wort is also increased with higher temperatures, aeration, and higher contents of soluble nitrogen. The process is the same as the one that occurs during kilning, the Maillard reaction (MacLeod, pp. 73–81).

During the wort boiling, hops, whole or powdered, are added to give their characteristic bitterness and aroma to the beer and, because of their antimicrobial action, to increase its shelf life. Principally, there are two types of acids contributed by the hops:  $\alpha$ -acids such as humulone, cohumulone, and adhumulone; and  $\beta$ -acids such as lupulone, colupulone, and adlupulone. The bitter taste of fresh hops derives almost entirely from the  $\alpha$ -acids, but they have only limited solubility in the wort. However, during the boiling, the  $\alpha$ -acids are transformed into soluble, bitter iso- $\alpha$ -acids, which contribute to the hoppy bitterness of the beer. There are at least six cis- and trans-iso- $\alpha$ -acids and their overall level in beer is about 0.0002 to 0.0005 oz/gal (Neve, pp. 33–38). The  $\beta$ -acids are largely unchanged during boiling.

The aroma of the hops comes from a very complex mixture of compounds and most of the volatile hop oils are lost in boiling, but a late addition of aroma hops increases the flavor. A discussion and list of the hop compounds in beer is found in Hardwick ("The Properties of Beer," pp. 573–577).

**Fermentation.** The principal pathway for carbohydrate metabolism is the Embden–Meyerhof–Parnas pathway, which is the anaerobic metabolism of glucose to pyruvates and alcohol by the yeast cells:

1 mole of glucose gives 2 moles of pyruvates, which will give 2 moles of alcohol and 2 moles of carbon dioxide (CO<sub>2</sub>).

A more comprehensive equation that describes a brewery fermentation is given by Bamforth (p. 143):

Maltose (100 g) + amino acid (0.5 g)  $\rightarrow$  yeast (5 g) + ethanol (48.8 g) + CO<sub>2</sub> (46.6 g) + energy (50 kcal)

Glucose and fructose are the first carbohydrates to be absorbed by the yeast cells from the wort. For the up-

take of maltose, the principal sugar of the wort, maltose permease must be synthesized, and before maltotriose can be used, the maltose of the wort has to be almost completely depleted. The formation of maltose permease is the time-limiting effect on the speed of fermentation of the wort. This enzyme is also inhibited by glucose, thus yielding a longer lag period in glucose-supplemented wort (MacLeod, pp. 81–103).

Amino acids can be divided into four groups according to their uptake into the yeast cells: A, B, C, and D in that sequence for both *S. c. cerevisiae* and *S. c. carlsbergensis*. The A and C amino acids appear to compete with the same permease. Proline, which is the only member of the D group, disappears very slowly, implying that a substantial amount of this amino acid will remain in the final beer: about 0.003 to 0.004 oz/gal.

Unwanted products from the fermentation process, which are closely related to amino-acid metabolism, are certain higher alcohols: 3-methylbutanol, fusel alcohol, and vicinal diketones (diacetyl). Presence of diacetyl seems to depend on a deficiency of the amino acid valine. A deficiency of methionine or an excess of threonine gives unacceptable levels of hydrogen sulfide (MacLeod, p. 91). Consequently, careful control of the amino-acid composition of the wort is essential. Esters (e.g., ethyl acetate) are also important as taste- and aroma-producing compounds. Their formation is favored by high-gravity brewing followed by dilution, ample supplies of assimilable nitrogen, and relatively high concentrations of alcohol (MacLeod, pp. 81–103). For further discussion on fermentation, see Munroe (1995, pp. 323–353).

The wort is rather rich in B vitamins, but this content, particularly the content of thiamine, is decreased during fermentation by the yeasts (Hardwick, pp. 576–577).

**Aging and finishing.** Newly fermented beer, often referred to as green beer, has to mature in flavor through storage at low temperatures and should be removed from the yeast. It may also require being clarified, stabilized, carbonated, blended, or standardized. The processes involved include filtrations, CO<sub>2</sub> additions, pasteurization, and additions of tannic acid and proteolytic enzymes for clarification of the product. For a more detailed discussion, see Munroe (pp. 355–379). Storage of green beer together with its yeast cells decreases the amount of diacetyl and 2,3-pentanedione, which have a buttery taste that is undesirable in lighter beers. Sulfur-containing compounds, such as hydrogen sulfide, sulfur dioxide, and dimethyl sulfide, may also show up in the beer, producing unattractive flavors and aromas.

During storage, a secondary fermentation can be performed to accelerate aging and the maturation of taste. A secondary fermentation can also be performed in the bottle, as is done in many Belgian ales and Trappist beers, for example. Another method used is to add up to about 20 percent of highly fermenting primary beer (*high-kriäusen*) to the green beer in storage. Also during stor-

age, aroma hops may be added to increase the aroma of the beer, and iso- $\alpha$ -acids from hops can be added to help control bitterness in the beer.

Modern industrial processes of aging and finishing beer, with ultrafiltrations, pasteurization, and total separation of yeast cells, give the modern-style clear, “dead” beer, which has a long shelf life. This contrasts with “real” beer or ale, which retains living yeast cells and thus exhibits richer taste and aroma, but has a shorter shelf life and often greater variation in taste and aroma. Most lagers do not contain yeast cells, but many bottom-fermented beers such as *Weissbier mit Hefe* (literally, “wheat beer with yeast”), Belgian beers, and British ales and stouts do. A comprehensive summary of the chemical constituents and the physical properties of beer can be found in Hardwick, “The Properties of Beer” (pp. 551–585).

**Beer aging and oxidation.** Beer is a fresh food product, which undergoes chemical changes during storage. Some of these are expressed as sensory changes shown in the schematic graph given by Bamforth (p. 68). The progression of these changes has been described by Dalglish (1977, cited in Fix):

Stage A is the period of stable, “brewery-fresh” flavor.

Stage B is a transition period in which a multitude of new flavor sensations can be detected.

Stage C products exhibit the classic flavor tones of beer staling.

Stage D, not included in Dalglish, “is the development of ‘kaleidoscopic flavors,’” as exemplified in Rodenbach’s Grand Cru and in Trappist beers, “recalling the subtlety and complexity of great wines” (Fix, pp. 127–128).

Most of these changes are due to a range of oxidative reactions in the beer. Hence, it is extremely important for the quality and shelf life of beer that the beer be oxygen-free. The alcohols in beer can be oxidized to aldehydes and acids, and the iso- $\alpha$ -acids can also be oxidized, with the formation of free fatty acids. All these compounds have prominent effects on aroma and taste. Free fatty acids can also form esters with the alcohols and the unsaturated fatty acids as well as the melanoidins produced via browning of the malt can undergo auto-oxidation. The fatty acids will give fatty and soapy flavor notes. Melanoidins may oxidize alcohols to aldehydes or acids. However, melanoidins can also be reduced by the oxidation of iso- $\alpha$ -acids and work as antioxidants, thereby protecting the beer from oxidation, as is the case in dark beer. The same effects are seen from malt- and hop-based phenols. Together with fatty acids, they interact in a complex electron exchange system.

The different kinds of phenols, from catechin to polyphenols (also called tannins and flavonoids), which originate from the malt, the hops, and also from the fermentation process itself play a large role in these chemical reactions. They can act as useful antioxidants in the

beer and add to the sensory impression of freshness. However, if they themselves become oxidized, they contribute astringency and harshness. Another very important result of the chemical reactions is the reduction of unsaturated fatty acids. This inhibits the development of long-chained unsaturated aldehydes, such as trans-2-nonenal, which is a prominent factor for the development of staling and cardboard and/or papery notes. Because of these reactions, highly hopped beer is less prone to develop the staling effect (Fix, pp. 127–139).

### Beer and Social Use

Throughout history, beer-drinking peoples have considered beer an essential part of both their food supply and their enjoyment of life. Bread and beer—food and beverage—were two parts of nutrition united via having almost the same process of fabrication. In earlier times, beer was thought of as liquid bread. As a beverage, it was also preferred over water, partly because water was often contaminated by bacteria, whereas beer became almost sterilized through the boiling of the wort and the antiseptic qualities of hops.

Beer and other alcoholic beverages have played a very important religious and social role: maintaining ties within groups and between people and their deities. It is not surprising that man has considered intoxicated humans to be in close contact with the deities and acquiring spiritual and supernatural forces from them. In Old Norse mythology, mead (an alcoholic beverage fermented from honey) gave humans immortality, wisdom, and poetic abilities. Mead and beer were considered to contain the spirit of the gods, and hence people ingested the gods by drinking the beverages in the same way as Christians drink the blood and eat the flesh of Christ at communion, in the form of bread and wine (Thunaeus, vol. 1, pp. 17–24; Wiegelmann, pp. 533–537).

At the ceremonial feasts of the Nordic people in the tenth century, the beer and food were first blessed and then highly ornamented horns of beer went to everybody to make toasts to the gods: to Odin for victory and power for the king, and then to Njord and Frej for a good harvest and peace. Then they drank *minne*, memory, for their ancestors and relatives. The ceremony formed and strengthened bonds both between the gods and men, and among men (Thunaeus, vol. 1, pp. 17–24; Wiegelmann, pp. 533–537). In medieval times and persisting until the nineteenth century, important ceremonies such as baptisms, weddings, funerals, and harvest celebrations had *öl*, beer, in their names; there were, for instance, *dopöl*, the celebration of baptism, and *gravöl*, the funeral feast. For the various celebrations, a strong beer was produced. On other days, a much weaker beer was consumed, which was sometimes even mixed with milk. People showed their hospitality by having a tankard with beer standing on the table, and everyone was welcome to take a sip.

These examples from the Nordic countries exemplify the general pattern of mankind using alcoholic bev-

erages as ceremonial links to the gods and a method of creating and increasing social contacts among people. Many of these ceremonies and social implications of drinking together are still active today.

### Mixtures of Beer and Other Beverages

In *Berliner Weisse*, juices of red raspberry, green sweet woodruff, or, more recently, pineapple may be added. To Belgian Lambic, different fruits can be added to the second fermentation to create, for example, *Kriek* (using cherries) and *Framboise* (using raspberries) (Jackson, 1991, pp. 95–100).

The English shandy (beer mixed with lemonade or ginger beer) and the German *Radler* and *Alsterwasser* (beer mixed with a clear soft drink, typically lemon or lemon-lime soda) are quite popular today. Shandy has a tradition that dates back to the tenth century (Zotter, pp. 222–223). *Alsterwasser* has also become popular with cola and tequila (Pini, pp. 88 and 788). *Radler* was earlier a common mixture for children and young people in Germany. In southern Sweden, the mixture of beer (*svagdricka*) and milk called *drickablandning* (mixture of drinks) was very popular until about the middle of the twentieth century.

### Food and Beer

Beer is used as an ingredient in food preparation in soups and stews, for marination of meat, as a liquid for boiling, and in sauces. Many German examples are given by Lohberg (pp. 269–331). Traditional soups with beer in northern Europe are *Biersuppe*, *Öllebröd*, and *Öksupa*, which are boiled mixtures of beer and meal and/or milk and egg, with ginger, cinnamon, and fruits. *Carbonade*, beef stewed in beer, is a favorite dish in northern France, Belgium, and the Netherlands.

The specific types of beer used traditionally in an area almost always fit very well with traditional local food. The most popular type of beer in the world today, pilsner or light lager, which is served cold and has low levels of bitterness and maltiness, is a good partner with almost any kind of food, which may well be an important reason for its popularity.

Other types of beers, which have a more complex taste, should be paired with different foods using some care, as the combination should not overpower the individual flavors of either the beer or the food, but enhance the positive features of both. A nice introduction with illustrative food and beer combinations has been presented by Jackson (1998). In general, beer can be paired with different kinds of food as well as wine can be, and sometimes better.

### Service Traditions

**Drinking vessels and beer containers.** In Latin America, the Incas and the Mayas developed very elaborate containers both for the production of *chicha* and for storage and ritual drinking. The malting and fermentation

took place in hollow tree trunks that were often decorated and covered with carpets or palm leaves. The bottles were ceramic stirrup vessels with a long neck, sometimes two joined into one, with a round bellow that could be formed as a human head. Ordinary ceramic cups were also used. The ceramics were painted with many different scenes, often with a strong erotic touch. Bottles filled with *chicha* were buried with the dead (Rätsch, p. 103).

The serving of beer in Mesopotamia and in ancient Egypt was from ceramic containers, both large ones from which people drank with straws (primarily to penetrate the top-fermenting yeast and floating husks) and smaller ones like our cups. For ceremonial drinking, elaborate bull's horns were used in northern Europe. After the ceramic period and persisting into the twentieth century, the wooden barrel and the wooden tankard were the principal storage and drinking containers. In Scandinavia, it was common to have elaborate drinking bowls, often in the form of a goose, for ceremonial feasts, and during the sixteenth century, the upper class used ornamental wooden drinking vessels (Hirsjärvi, pp. 57–68; Cleve, pp. 15–42; Gjærder). Drinking vessels were also later made of lead, tin, copper, silver, stoneware, ivory, china, or glass. Tankards usually had the same general design whether or not they were lidded. Lids were usually metallic, and the rest of the tankard was made of glass, ceramic, or wood. There were very elaborate, expensive tankards and also simple and practical ones (Jung; Lohberg).

Although its history is very long, perhaps as long as the history of beer itself, before the nineteenth century the beer glass was seen only among the upper classes. It was the technique of glass pressing in great industrial scale in the nineteenth century that made the glass available to everyone. The design of the beer glass has developed in some distinctive ways, with special sizes and shapes for specific types of beers and special glasses displaying the names and logos of the brewers for almost every brand of beer (Lohberg; Jackson, 1998). Jackson includes color images of both the glass and the bottle for each type of beer presented in the book.

The original wooden barrel was generally replaced in the twentieth century by the steel barrel. At the end of the nineteenth century, glass bottles were introduced, and beginning in 1935, they were joined by metallic containers—beer cans.

**Serving temperature.** There is a correct serving temperature for every beer. The richer the flavor and aroma of a beer is, the higher its serving temperature should be. A very low temperature is suitable if taste is secondary. The only beers that are appropriate to serve cold, about 39°F (4°C), are light, pale lagers. More tasty lagers should be served between 43 and 50°F (6 and 10°C), and ales between 54 and 64°F (12 and 18°C). Jackson (1998) is a good source for recommendations of serving temperatures for specific beers.

## DRINKING ESTABLISHMENTS IN EUROPE

The establishments for serving beer in Europe have developed into three different lines or beer-serving cultures:

- The Central European in the area of South Germany, the Czech Republic, and Austria: The *Bierkeller* or *Biergarten* has no bar but rather big wooden tables, chairs, or benches; the beer (only a few brands) is served from barrels. The glasses are specific for the type of beer served. In Munich the beer could be served in a tankard of glass or ceramics, *ein Mass* (which means one tankard) of either one or two liters.
- The British: The pubs have a bar around which most of the people gather. Some real ales, a stout, and a light lager from kegs are served in pint glasses.
- The Belgian: The typical cafés have some resemblance to the French or the Austrian cafés serving wines and coffee. The number of brands of beer offered is great—up to the hundreds in some cafés in Belgium.

In all three types of establishments the food served is simple but in most cases nourishing.

## Beer and Traditional Medicine

Hans Zotter's book (pp. 222–223) contains medical recommendations and rules from Ibn Butlan from the tenth century. It illustrates how beer was looked upon medically in the old tradition of Hippocratic medicine, a tradition that prevailed until about the seventeenth century. Its view was that

Beer is “hot and humid”; or “cold and humid.”

The best beer is sharp and spicy.

Beer drinking relieves the sharpness of heat and drunkenness.

It dilates the vessels and creates discomfort.

In contrast, the mixture of beer and lemon juice or citric acid helps.

Beer drinking creates “malicious body fluids,” which are good for people with hot “complexion” and for young people, especially during hot weather and in hot countries.

In 1614, the philosopher and alchemist Paracelsus wrote: “Cerevisia malorum divina medicina” (Beer is a divine medicine against harms) (Rätsch, pp. 12–14). Beer was also used as a carrier or solvent for many different folk remedies (Rätsch, pp. 28–40). The use of herbs and

spices, such as hops and sweet gale, in beer may well have its origin in folk medicine.

Interestingly, beer is still prescribed today in the United Kingdom as a medication for the elderly.

**BEETON, ISABELLA.** Isabella Beeton (1836–1865), author of *Beeton's Book of Household Management*, was born at 24 Milk Street, Cheapside, London, as Isabella Mary Mayson, one of four children of Benjamin and Elizabeth Mayson. Isabella was educated at Heidelberg, Germany, and became an accomplished pianist.

When she returned from Germany, and while visiting family and friends in London, she met the wealthy publisher Samuel Orchart Beeton. Samuel Beeton, a publishing genius, possessed a talent for capitalizing on Victorian market trends. Part of the new and prosperous middle class, he published popular literature and *Beeton's Book of Garden Management* and *Beeton's Book of Universal Information*. Isabella and Samuel were married on 10 July 1856 and settled in the London borough of Harrow.

Their marriage was a fruitful professional collaboration: He was enthusiastic and creative, while she was a meticulous, level-headed researcher with an eye for detail. Beeton encouraged Isabella to compile her recipes and household management tips into articles written for *The Englishwoman's Domestic Magazine: An Illustrated Journal Combining Practical Information, Instruction, and Amusement* (EDM). She eventually assumed editorial responsibilities for EDM, and also for the Beeton's new journal, the *Queen*. She was soon working regularly at Samuel's office at the Strand, in an era when very few women worked in an office. While writing and editing for Samuel's magazines, and despite the loss of her first child, Isabella was already researching and gathering data for her magisterial work, *The Book of Household Management*. She also found time to open a soup kitchen at her house in the winter of 1858 to feed the poor children of Hatch End and Pinner.

According to Nicola Humble, the editor of the 2000 edition of *Mrs. Beeton's Book of Household Management*, the book remains one of the great unread classics of our time, though a highly collectible one. Published in October 1861, *Mrs. Beeton's Book of Household Management* (BHM) sold 60,000 copies and nearly 2 million by 1868. Orig-

nally published as monthly supplements in EDM, the first installment appeared in September 1859 when Isabella was twenty-three.

The BHM, as Humble notes, is much more than a cookery book. Its comprehensive range of recipes and household management techniques (2,751 entries) speaks to a culture that was caught up in the social changes of mid-nineteenth-century urban England. The BHM is also a sort of window into the Victorian social life of kitchens and household, giving all manner of instructions on etiquette, on the handling of servants, the economic spaces of kitchens, child rearing, medical advice, and animal husbandry. The book is also noted for some famous maxims, including, "A place for everything and everything in its place." Isabella Beeton herself never claimed that the recipes were original, and her preface acknowledges correspondents from Great Britain and Europe for their ideas. She adapted recipes from Alexis Soyer's *Modern Housewife* and Eliza Acton's *Modern Cookery for Private Families*, and, though she cites Soyer, she does not give credit to Acton. What Isabella Beeton did do was test the recipes herself, and any recipe she found uneconomical, impractical, and difficult, she discarded. If she was not an original cook, she was supreme in her organizational skills, arranging the recipes in alphabetical order, listing estimated costs, and producing clear, concise instructions for all food preparation and cooking as modern cookbooks do. It is worth noting that the BHM is not the first of its kind, and that Hannah Glasse's *The Art of Cookery Made Plain and Easy* (1747) also included household improvement tips and simplified cooking techniques.

Isabella Beeton became ill after the birth of a child, and died of puerperal fever at age twenty-eight—but not before completing the editorial work on *Mrs. Beeton's Dictionary of Cookery*. Samuel Beeton died of tuberculosis twelve years later, in June 1877. The Beeton's are remembered by a road, Beeton Close, near their old home at Hatch End, which was bombed out during a German air raid in September 1940. The BHM has since been reprinted numerous times, and Isabella Beeton's life has been turned into the one-woman show *Bella* by Alison Neil and adapted for BBC radio in 2002 by Tony Coult.

**BERIBERI.** Beriberi is a disease that usually begins with a loss of feeling in the feet and then weakness and pain in walking. In many, but not all, cases the body then becomes swollen and in the most serious cases the heart begins to fail, and the patient becomes breathless and soon dies. The problem stems from an insufficient intake of the vitamin thiamin (or "thiamine") even though we require each day only about 1 milligram, which is equivalent to one 32,000th of an ounce. The word "beriberi" comes from Indonesia and may mean "weak" or "swelling," but there have been many other suggested meanings.

The disease used to be a serious problem in Far Eastern countries where white rice was the staple food and people ate only small quantities of supplementary foods. Husked rice grains provide a reasonable amount of this vitamin, but further processing, or "polishing" to rub off the bran and germ, removes most of the remaining thiamin. Washing the grains and boiling them leaves even less thiamin in the final cooked food. Unfortunately, brown (unpolished) rice goes rancid more quickly under tropical conditions and so has only a short storage life. In traditional peasant communities, where enough paddy (unhusked grain) would be pounded and winnowed each morning for the day ahead, this was not a problem. When inexpensive power machinery for milling and polishing rice was developed, this made the provisioning of the armed forces in particular much more convenient, but in Japan and other Asian countries it was followed by serious outbreaks of beriberi in the army and navy.

Infantile beriberi also has been a major cause of death among breast-fed infants in the Philippines and other communities where mothers are in a state of borderline, subclinical thiamin deficiency. Affected infants typically cease to pass urine and experience difficulty in breathing. Even those near death, however, respond dramatically to a dose of thiamin.

It is technically possible now to mix in with white rice a few vitamin-rich pellets manufactured to resemble rice grains. However, where rice-growing communities each have their own small village mill, it has been found impracticable to control such additions, which slightly increase the millers' costs. As an alternative, communities at risk can be supplied with inexpensive vitamin pills.

In developed countries thiamin deficiency is still a problem among alcoholics, partly because such addicts have highly abnormal diet patterns and partly because they seem to absorb the vitamin less efficiently. They also may show acute heart problems without any early symptoms of traditional beriberi. A small proportion progress to a syndrome with irreversible brain damage that requires indefinite hospitalization.

In many Western countries, millers are required to fortify white wheaten flour with thiamin (along with other micronutrients). Thus, even the population groups, such as alcoholics, who are eating an unbalanced diet are

less likely to become deficient. It also has been suggested that alcoholic drinks should be fortified with thiamin. This would not be prohibitively expensive, but authorities have felt that, on balance, it would be undesirable because it would allow them to be marketed as "health drinks" despite the injurious effects associated with or caused by alcohol consumption, that is, automobile accidents, disruption of families, and a wide range of health problems.

Carpenter, K. J. *Beriberi, White Rice, and Vitamin B*. Berkeley: University of California Press, 2000.

Williams, R. R. *Toward the Conquest of Beriberi*. Cambridge, Mass.: Harvard University Press, 1961.

**BERRIES.** Wherever humans have lived, berries have been a part of their diet. Most of these have never developed beyond local markets but some have become globally important crops. Historically, berries were eaten fresh or processed into dried or fermented products. Many descriptions of indigenous American culture describe smoking and/or drying berries that are mixed with some sort of meat product to form pemmican. As sugar became commonly available as a preservative, jams, preserves, and jellies became popular. With the development of the canning industry in the late 1800s, the freezing industry in the mid-1900s, and the global transportation system in the late 1900s, long-distance distribution and long-term storage began to spread a handful of berry crops throughout the world. Today, in any large grocery, fresh berries are available year round. Whereas berries used to be found only in the fresh produce and dessert sections, they are now found in every section as well as in the adjacent health food store as a nutritional supplement and in the liquor store as wine and distilled spirits. Historically, berries were welcomed as a pleasing and nutritious addition to a drab table. While this has not changed, the increased value placed on nutraceutical foods is likely to expand berry consumption even further. (Nutraceutical foods, also called functional foods, are foods that provide a medical or health benefit beyond the traditional nutrients they contain.)

Market globalization has led to the development of a group of major crops, often at the expense of still popular regional crops. This discussion is largely limited to the most economically important and well-known temperate "berry" crops that are produced on a shrub or a perennial herbaceous plant, including: strawberry (*Fragaria X ananassa*), blueberry (*Vaccinium corymbosum* and *V. angustifolium*), cranberry (*V. macrocarpon*), black cur-

rant (*Ribes nigrum*); red raspberry (*Rubus idaeus*), black raspberry (*Rubus occidentalis*), and blackberry (*Rubus* sp.).

### Strawberry (*Fragaria*)

**Plant biology.** The cultivated strawberry (*Fragaria X ananassa*) is a low-growing, herbaceous perennial in the rose family (Rosaceae). Trifoliate leaves are produced from a crown as are the flowering trusses and runners. The hermaphroditic (both sexes present) flowers have white petals with many stamens surrounding a pistil-covered receptacle. The showy flowers are insect pollinated. Following successful pollination and fertilization, the achenes (seeds) set, and the receptacle tissue below the achenes swells and ripens. The crown also produces runners, which are elongated stolons that can root and form new “daughter” plants.

**History.** Strawberries are believed to have been cultivated in Greek and Latin gardens and they were mentioned by Pliny the Elder (23–79 C.E.) in his *Natural History*. Darrow reprints many examples of the use of strawberry in Christian religious art of the 1400s. The “X” in the Latin name for the cultivated strawberry, which indicates that it is a hybrid between two species, points to its interesting background. The Mapuche and Huilliche people of Chile were cultivating the native *F. chilensis* at the time of the Spanish conquest in the mid-1500s and the plant was counted by the Spaniards as a spoil of war that they carried north into Peru and Ecuador. In 1711, Amédée François Frézier was commissioned by King Louis XIV of France to sail to Chile on an intelligence mission. In addition to mapping and observing Spanish activities, he explored the botany of the region. Five plants from Concepción survived the six-month voyage back to France in 1714. Frézier did not realize that the wild species are largely dioecious (separate male and female plants) and he had only collected female plants. As a result, these Chilean treasures were very uneven in their performance, producing little if any fruit in France. After many years of observation, gardeners realized that the plants were productive when grown with *F. virginiana*, the meadow strawberry, which the Europeans brought back from their colonies in eastern North America. Regardless of whether the hybridization of these two American species in France was intentional or happenstance, the result was the cultivated strawberry.

*Fragaria chilensis*, the beach strawberry, ranges from Alaska to the central California coast in North America and Chile, primarily on dunes within the fog zone adjacent to the Pacific Ocean. *Fragaria virginiana* ranges throughout much of temperate North America except for the drier regions. New germ plasm (wild representatives of a species) from these two species have been used over time to introduce new traits into the cultivated strawberry and, in one case, this led to a revolution in the industry. While most strawberries produce flower buds in response to the shortening days of late summer and go

The *Witte Hollander* or White Dutch Currant, one of the oldest strains of white currants surviving from the late 1600s. It was developed in Holland and introduced into English and American gardens in the 1720s. ROUGHWOOD SEED COLLECTION, PHOTO WILLIAM WOYS WEAVER.

on to fruit the following spring, one population of *F. virginiana* from the Wasatch Mountains in Utah was found in the 1960s that, when grown in California, flowered and fruited regardless of day length. This “day-neutral” trait was incorporated into commercial cultivars and allows for nearly year-round production of fruit throughout the world.

**Production, processing, and distribution.** California is the most important production area in the world, and cultivars and production techniques developed there are commonly used throughout the world. Strawberries for the wholesale fresh market are grown on fumigated soils with plastic mulch and drip irrigation. The plants are primarily grown as an annual crop. Fruiting begins about two months after planting and continues for seven to nine months, after which the plants are removed. Fresh market strawberries are harvested directly into plastic

clamshell packages that are then shipped under refrigeration. Strawberries for the processed market are either a by-product of the fresh market, that is, those that are too small or malformed, or they are harvested from cultivars specifically designed for the processed market. Processing cultivars have intense color and flavor, and maintain their integrity after processing. Strawberries are canned and dried but the primary raw processed products are as frozen IQF (individually quick frozen) berries, sugar and sliced packs, purees, or as juice. A tremendous diversity of consumer products are made from these primary raw products.

Strawberries, as with most berries, once had to be consumed locally due to perishability; however, with improved cultivars, production practices, packaging, and transportation, fresh fruit can be shipped long distances from the growers' fields.

Strawberries are a valuable source of vitamin C, fiber, folic acid, and anthocyanins (red pigment). Anthocyanins have been recently recognized for their nutraceutical benefit as antioxidants in human nutrition.

### **Red Raspberry, Black Raspberry, Blackberry, Caneberry, Bramble (*Rubus*)**

Red (*Rubus idaeus*) and black raspberry (*R. occidentalis*), and blackberry (many diverse *Rubus* species), are the most important crops in the genus *Rubus*. In addition, some of the hybrids between red raspberry and blackberry such as "Boysen" and "Logan" and other species such as the cloudberry (*R. chamaemorus*) in Scandinavia, the wineberry (*R. phoenicolasius*) in Japan, the mora (*R. glaucus*) in Andean South America, and the trailing raspberry (*R. parvifolius*) in Asia have become regionally important crops. As a group, these species are often referred to as "caneberries" or "brambles."

**Plant biology.** Members of the Rosaceae discussed above have perennial root systems and biennial canes. With one exception, these biennial canes are vegetative the first year (primocanes) and produce fruit the second year (floricanes) before dying. The primocane/fall fruiting raspberries and, in the near future, blackberries are the exception, as they flower and produce fruit late in the season on first-year canes. Floricanes break bud in the spring and produce flowering branches with many insect-pollinated flowers. Flowers have white or light pink petals with a ring of many stamens that surround a pistil-covered receptacle (also called torus). After pollination and fertilization, each of the individual ovaries develops into a drupelet, which collectively form the aggregate fruit. Raspberries are differentiated from blackberries based on whether the torus remains on the plant when the fruit is picked (raspberries) or whether it is picked with the fruit (blackberries).

**Raspberry history.** Red raspberry is native throughout the colder temperate regions of the Northern Hemisphere and black raspberry throughout the midwestern

and mid-Atlantic regions of the United States. The first red raspberries were introduced into cultivation in Europe about 450 years ago, according to Hedrick, and European cultivars were brought to North America prior to 1800. Black raspberries were commonly picked from the wild in North America and the first named cultivars began appearing in the 1850s.

**Red raspberry.** While raspberries today are grown throughout the world in temperate regions, their production is concentrated in eastern Europe and the Pacific Northwest of North America. Berries from these two regions are primarily processed as IQF, purees, or juice, and these basic raw products serve as the basis for innumerable consumer products. Trellised, irrigated, long-term, perennial plantings that are mechanically harvested are standard for the processing industry. Production for the fresh market is evolving rapidly, with California and Mexico as the production centers for the Americas and Germany in Europe. Chile, New Zealand, and Australia are the major suppliers of fresh fruit during winter in the Northern Hemisphere. For the fresh market, plants are grown either in a perennial system or, as in California, for one and a half years, during which two crops are produced, and then the plants are removed. Fruit for the fresh market are hand-picked and generally produced under protective plastic hoop structures.

**Black raspberry.** While there are many scattered small plantings of black raspberries throughout North America to serve local fresh market needs, the bulk of the industry is concentrated in Oregon's Willamette Valley. Black raspberries are grown in hedges about one by one meter in short-term (three- to four-year) perennial plantings that are machine harvested. While some black raspberry jam is produced, the berries are primarily processed as juice and often used as a natural colorant.

**Blackberry.** Blackberries are native throughout Eurasia and the Americas, although the primary commercial cultivars were developed from species native to North America. Erect and semierect cultivars were derived from eastern North American species and these can be characterized by being upright-growing, firm-fruited, large-seeded, and more suitable for the fresh market than for processing. These types are generally grown in small, long-term, perennial plantings throughout the United States, with a higher concentration of acreage on the western coast of the United States. For the processing market, the trailing blackberry cultivars, particularly "Marion" (often called Marion berry), are grown in long-term, trellised plantings that are harvested by machine for the processing market. This industry is concentrated in Oregon's Willamette Valley, although Mexico is expanding production. Fruit is processed as IQF, purees, and juice, and these are used to produce many consumer products.

**Variations in regional demand.** Demand for the various types of caneberries shows marked geographical

trends. Since the caneberries have always been picked from the wild near where people have lived, there are many small but regionally significant industries that have developed around these crops. While red and black raspberry and blackberry dominate the worldwide market, travelers in Andean South America or Scandinavia will find an abundance of products made from the regionally grown mora or cloudberry, respectively. In North America, the region where one grew up often influenced what kind of caneberry one preferred, with southerners preferring blackberry and northerners preferring red raspberry.

**Uses and nutrition.** Until the late part of the 1900s, raspberries and blackberries were primarily used to make jams and jellies or desserts. Now these crops have been incorporated into myriad products that require juices. Blackberries and raspberries are an excellent source of vitamin C, calcium, fiber, iron, and folic acid. The increased interest in nutraceutical products focuses special interest on these crops. While blueberries and cranberries have been touted for their proven health benefits, the anthocyanins (pigments that give the fruits their red and purple colors), which are powerful antioxidants, are even more concentrated in blackberries and raspberries, especially in black raspberries.

### **Blueberry, Cranberry, Lingonberry (*Vaccinium*)**

**Plant biology.** Blueberry, cranberry, and lingonberry are all long-lived perennial crops in the Ericaceous family. These crops were originally native to acidic and moist soils with high organic matter levels in cool temperate regions of the Northern Hemisphere. Blueberries are upright-growing plants with long-lived perennial canes. Highbush blueberry (*Vaccinium corymbosum*), native to the eastern United States, is a shrubby, crown-forming bush (1–2.5 m) and is the basis for most of the cultivated blueberry industry. Lowbush blueberry (*V. angustifolium*), native to the northern United States and southern Canada, is a small bush (0.5 m) that spreads by underground stems. Managed wild stands of the lowbush in eastern Canada and eastern Maine are the basis for the “wild” blueberry industry. Cranberry (*V. macrocarpon*) is a creeping plant that produces fruiting uprights and is native to boggy areas of the northern United States and southern Canada. Lingonberry (*V. vitis-idaea*) is a short-statured (0.3 m) plant that spreads by underground stems, and while it is found circumboreally, it has been primarily developed into a crop in Scandinavia and northern Europe.

**Blueberry.** Blueberries produce clusters of hanging bell-shaped white or light pink flowers in the spring. The insect-pollinated flowers swell to form a true berry that contains many very small seeds. When ripe, the fruit have a bluish black skin covered by a waxy bloom that gives them their bright blue appearance.

Blueberries are truly an “all-American” crop, as they were native to this continent, developed as a crop on this continent, and, until the late 1900s, were not well known

outside of this continent. In the early 1900s, a grower in New Jersey began to work with the U.S. Department of Agriculture (USDA) to develop improved blueberries. From these modest beginnings, the USDA went on to release all of the cultivars, which led to highbush blueberries’ rise from a little-known “swamp plant” to one of the most important berry crops worldwide. While lowbush blueberries have not been changed by breeding, the production practices have become highly developed since the first Europeans harvested the expanses of mixed lowbush blueberry and forest lands in Maine and eastern Canada that Native Americans had harvested for generations.

Highbush blueberry production is concentrated in North Carolina, New Jersey, Michigan, and the Pacific Northwest, and the much smaller European industry is primarily in Germany and France. Chile, New Zealand, and Australia are major suppliers in the winter months in the Northern Hemisphere. Today plants are grown on ridged plantings, with irrigation and pest control, and they are harvested by machine for processing markets. The berries for the fresh market are harvested, cooled, packed in plastic clamshells, and shipped around the world. Fresh blueberries are often stored for up to two months in a controlled atmosphere.

Early growers and commercial canners recognized that if they burned their “wild” lowbush fields every other year, they could more easily harvest the abundant fruit in the intermediate year. Field burning not only managed growth, but it eliminated many of the competing plants, insects, and diseases. While lowbush blueberries were never planted by man, they are really no longer “wild” since the larger commercial operations are intensively managed, as are the highbush blueberries. Lowbush blueberries are harvested by hand with rakes and, where the ground surface area permits, by machines for processing.

Lowbush and highbush blueberries are processed as IQF, purees, juice, and dried products. One of the reasons that blueberry consumption and production rose so dramatically at the end of the twentieth century was their suitability for many processed products (for example, they have no noticeable seeds or pits, they blend well with other products, and their flavor is not intense so they can be used very widely).

Blueberries are an excellent source of vitamin C and fiber. Anecdotal stories from World War II attributed the supposedly better night vision of British pilots to their consumption of bilberry (*V. myrtillus*) jam. Decades later, in the 1990s, the benefits of bilberry to the health of microcapillaries and as a powerful antioxidant were documented by medical research. Subsequently, blueberry, which is more readily available for mass consumption than bilberry, was studied and was found to have a similar chemical constituency, although sometimes at a lower concentration than in bilberry.

**Cranberry.** Cranberry, originally called “craneberry” by early immigrants to North America due to the shape

of the flower, was used by Native Americans as a food, a medicine, and a dye long before Europeans arrived. Native to northern temperate areas from Minnesota to the Atlantic Ocean, cranberries were first cultivated in Massachusetts in the early 1800s. While many cultural changes have improved production, most of the cultivars grown today are selections from the wild or superior plants found in growers' bogs. Bog establishment is a very expensive process that involves land leveling, water system management, soil amendments, and diking. Since the development of wetlands is tightly regulated in North America, establishing new bogs there is becoming increasingly difficult. The vining plants produce uprights that produce flowers. With insect pollination, the flowers are fertilized and the fruit develop. In early fall, the fields are flooded and specialized machines beat the fruit off the plant where they can float to the surface and be skimmed off into trucks. While many have the image of cranberries growing in water, they are actually not tolerant of flooding for extended periods, so fields are drained immediately after harvest. For commercial bogs in very cold climates, water is layered into the fields in early winter, and after each layer freezes, another is added, eventually covering the plants and protecting them from the harsh climate. Fruit is primarily processed into juice. A small portion of the crop is sold fresh for the Thanksgiving and Christmas holiday season, and there is a growing market for dried, sweetened cranberries ("craisins"). Cranberries have a long association with holidays, particularly American Thanksgiving. In 1959, just before the holiday season, a pesticide scare swept the United States, closing all outlets for fresh cranberries, and much of the crop was dumped. This disaster further spurred the development of a wider variety of products. The Ocean Spray growers cooperative, formed in the 1930s, did a remarkable job of expanding cranberry demand in the late 1900s, particularly through their well-known fruit juices.

Cranberry juice has been a well-known home remedy for women seeking relief from yeast infections in their urinary tract. In the 1990s, medical research documented that consumption of cranberry juice could cure yeast infections. In addition, cranberries are a rich source of vitamin C, fiber, and anthocyanins, which are powerful antioxidants.

**Lingonberry.** Lingonberries have always been closely tied with the people of Scandinavia and northern Europe, where much of the commercial crop is still harvested from wild stands. When cultivated, the plants are established in rows that fill in quickly with growing underground stems. Two crops are produced in long season areas; the summer crop is usually not harvested, but the fall crop is harvested for holiday sales. While machines are being developed to harvest lingonberries, hand raking is still the predominant method of harvest. Lingonberries most often remind people of a "mild" cranberry. As such, they can usually be used in similar

applications to fresh cranberries and are popular as preserves and relishes.

### **Black Currant, Gooseberry, Red Currant (Ribes)**

Gooseberries and currants are members of the Saxifrage family that have been prized in Europe and Russia for centuries but have not developed a strong market elsewhere. Gooseberries and red currants have very interesting histories, but their production is tiny compared to black currant and they will not be discussed in detail. Part of the reason that currants and gooseberries have not developed a following in the United States is that growing them has been banned in many states, as they are an alternate host for white pine blister rust, which can be devastating to the white pine timber trade.

**Plant biology, history, and production.** These crown-forming, long-lived perennial shrubs produce their fruit on woody, one-year-old, smooth canes (gooseberries have thorns). Buds along the cane produce strigs that have from eight to thirty flowers in the spring. The flowers are not showy, typically light green or yellow colored, but are attractive to insects for pollination. Black currants (*Ribes nigrum*) are native to the cooler regions of Eurasia and can tolerate extremely cold winter temperatures. Despite being found in close association with humans for a long time, they were largely used as a medicinal plant until fairly recently. Hedrick quotes an herbal from 1633 that says black currants are "of a stinking and somewhat loathing savour."

**Uses and nutrition.** Beginning in the 1900s, juice products from currants were developed, the most famous being Ribena, as it was recognized that the high vitamin C content of black currants could be maintained when juiced. In a sense, black currant juice has been to Europeans what orange juice was to Americans. In addition to vitamin C, black currants are a rich source of antioxidants, vitamin A, and calcium. Black currants are grown almost exclusively for processing as juice. Plants, primarily cultivars developed in the United Kingdom or Russia, are cultivated in hedgerows that are mechanically harvested. Fruit is bulk frozen and then juiced.

### **Lesser-Known Crops**

As was first mentioned, wherever humans have lived they have made berries a part of their diet, and as such there are innumerable berries not mentioned here that are part of the human diet. Some examples of other berries that have generated renewed or new interest, in addition to red currant and gooseberry, include aronia (*Aronia melanocarpa*), elderberry (*Sambucus nigra*/S. *canadensis*), sea buckthorn (*Hippophae rhamnoides*), juneberry/serviceberry/saskatoon (*Amelanchier* sp.) and edible honeysuckle (*Lonicera caerulea*) (Finn). However, unless they have unique characteristics, such as high nutraceutical value, they are unlikely to significantly impact the production and consumption of the major crops.

**BETTY CROCKER.** Betty Crocker, an American cultural icon, was created in 1921 by the advertising department of the Washburn Crosby milling company just before it merged with General Mills. The consummate homemaker who could answer any cooking question with ease, Betty Crocker was based upon several real women, the two most notable being home economists Janette Kelley and Marjorie Child Husted.

Neither her name nor her face, which has been updated numerous times, was real. Both, however, became synonymous with good cooking and competent homemaking through newspaper columns, radio programs, television spots, and the publication of over 150 cookbooks. Betty Crocker's most significant contribution came in 1951 with the publication of *Betty Crocker's Picture Cookbook*, which remains a top-selling cookbook today. Unlike the extremely thorough *The Joy of Cooking* by Irma Rombauer, *Betty Crocker's Picture Cookbook* helped women cook by including both large illustrations and recipes on one page.

Betty Crocker's image and what it represents has created an automatic acceptance by consumers of numerous General Mills products from breads to cake mixes. Perhaps more important, her icon status has given her an active role in American life. Betty Crocker has helped generations of American women over the years deal with challenges including food scarcity during the Depression and World War II, a renewed emphasis on homemaking in the postwar years, and the increasing sophistication of American taste. From cutting food costs to increasing women's satisfaction through cooking to adding new ingredients to update old recipes, Betty Crocker continues to keep her finger on the pulse of American life and to respond accordingly.

## BETTY CROCKER MAKEOVER

General Mills created Betty Crocker in 1921 as a kind of mother figure to promote the company's food products. Over the years, Betty has undergone a number of makeovers to keep her in tune with changing perceptions about homemakers and cooking. These eight pictures show how she has changed since 1936. One thing has remained consistent: she is always dressed in red. © AP/WIDE WORLD PHOTOS.

**BIBLE, FOOD IN THE.** Food and drink are everywhere in the Bible. Among the best-known scenes are the Last Supper (Mark 14:17–25; Matthew 26:20–29; Luke 22:14–23; John 13:1–14, 13:31), the feeding of the five thousand (Mark 6:30–44, 8:1–10), the feast for the lost son (Luke 15:11–32), and the wine miracle in Cana (John 2:1–12) from the New Testament and the first Pesach meal in Egypt (Exodus 12:1–13, 12:16); Abraham's sacrifice of Isaac, for whom a wild goat was substituted (Genesis 22:1–19); the manna in the desert (Exodus 16:31–35); and the recurring mention of the land flowing with milk and honey from the Old Testament. The function of food in the Bible is twofold. First, it offers information on what was produced and consumed in the area in biblical times, including how food was prepared and its meaning; second, it conveys messages to the reader.

## Attitudes toward Food in the Bible

Scientific interest in food in the Bible always has focused on, among other things, sacrifice and abominations (Bolle; Bourdillion and Fortes; Douglas; James; and Smith). The biblical sacrificial animal is rarely burnt entirely, as indicated in the descriptions of some specific sacrifices in Numbers 28 and 29 or Abraham's sacrifice. The majority of a sacrifice is consumed either by those who offer the sacrifice or by the priests (1 Samuel 1–2). Each food offering (the meat) is accompanied by a grain offering (flour and olive oil) and a drink offering (preferably wine,

One of the most popular food scenes in the Bible is the Marriage of Cana, which has allowed Christian artists down through the centuries to employ their creative talents on imagery drawn from their own life experience. Italian Renaissance painter Giotto di Bondone (d. 1337) created this dinner scene as it would have appeared in a nobleman's house around the early 1300s. © ARCHIVO ICONOGRAFICO, S.A./CORBIS.

but in some cases beer is acceptable) (Numbers 28–29). Sacrifices, usually offered at feasts, distribute precious animal protein evenly among the population and over time. A feast occurs on each new moon, and others follow in the middle of at least every second month.

The nature of the sacrifice follows the rules of purity described in Leviticus. No restrictions apply to the consumption of plants, but elaborate rules govern animal food. Animals are divided into three groups: animals on land, creatures in the water, and birds. Of these only a small sample are considered clean: “You may eat any an-

imal which has a parted foot or a cloven hoof and also chews the cud; . . . all those that have fins and scales,” and birds with two legs who fly and do not eat carcasses (Leviticus 11). The purity rules conform with the animals well adapted to the local climate and easily domesticated. Furthermore the food taboos keep the Israelites distinct from other peoples of the region, supporting their group identity. When Christianity starts to convert other peoples, the strict food rules become an obstacle and therefore are removed. According to Acts 10 it was revealed to Peter that nothing is unclean.

Meat is always in the foreground of biblical narratives on food, and it is the highly esteemed center of any festive meal, religious or secular. During their wanderings in the wilderness, the Israelites yearn for the fleshpots of Egypt (Exodus 16:2); in 1 Samuel 2:12–17 the priests demand a piece of good roast from the sacrifice instead of being content with whatever their forks catch from the cauldron; it is a sign of honor to be fed a piece of meat by the host (1 Samuel 9:23); and meat is essential to a covenant. Nevertheless, the staples are cereals (barley, wheat, emmer, spelt, millet, and sorghum). Barley, the most important, is mainly consumed as grits (porridge); wheat is valued higher and is baked into bread. The highly valued fruits include olives for oil, which is easy to store, and dates, which provide energy. Vegetables (leek, orache, onion), pulses (fava bean, pea, lentil, chickpea), fruits (apple, fig, pomegranate, melon, mulberry, grape), and herbs and spices (cassia, cinnamon, coriander, cumin, dill, garlic, ginger, laurel, mint, mustard, saffron, turmeric) are abundant.

### Situations of Consumption

Among the most prominent situations for consuming specific foods are feasts, covenant meals, carousals, and fasts. The majority of religious feasts consist of the sacrifice of animals—usually birds, sheep, goats, or cattle, depending on the means of the family—and the communal meal of the family. The important religious feasts are Pesach (Passover), Massot (Feast of Unleavened Bread), Shavuot (Pentecost), Rosh Hashanah (New Year), Yom Kippur (Day of Atonement), Succoth (Feast of Tabernacles), Hanukah (Festival of Lights), and Purim (Feast of Lots). Life-cycle festivals mentioned in the Bible include weddings, birthdays, and burials. For the wedding of Jacob and Leah, “Laban gathered all the men of the place together and gave a feast” (Genesis 29:22); when Samson marries, the party lasts seven days (Judges 14:12); Raguel tells his wife Edna “to bake a great batch of bread” and has two oxen and four rams slaughtered for the two weeks of celebrating the marriage of Tobias and Sarah (Tobit 8:20); Jesus compares heaven to the wedding feast of a king’s son (Matthew 22:1); the wedding party at Cana-in-Galilee runs short of wine, and Jesus turns water to wine (John 2:1–12). The only birthday party mentioned in the Bible is the Egyptian pharaoh’s, which turns out to be the day of destiny for the chief baker and the chief butler when one is hanged the other restored to his service (Genesis 40:20). The bread to console and the cup of consolation are the frugal nutrients for mourners, who often refuse to eat and drink for a short time after the death of a beloved or fast for a longer period to display their mourning.

The covenant meal as a pact between people or between God and his followers is a recurrent theme. This meal makes the oath binding forever by threatening the partners’ bodies with a curse. In case of perjury, the curse “may seep into his body like water and into his bones like oil” (Psalms 109:18). God’s covenants with Abraham and

Moses are sealed by the ritual slaughtering of several animals (Genesis 15; Exodus 24). When Jacob leaves Laban’s home, they swear an oath regarding the respective territories and have a feast with their kinspeople (Genesis 31:43–54). Joseph is sold to the passing tradesmen while his brothers “sat down to eat some food” (Genesis 37:25). Sharing provisions with the inhabitants of Gibeon, Joshua settles a pact with the Gibeonites (Joshua 9:14–15). Those who share a meal are obligees, but they frequently betray each other (Psalms 41:9; Proverbs 23:7; Mark 14:18). The New Covenant is made at the Last Supper (Matthew 26:17–30; Mark 14:12–26; Luke 22:7–39; John 13:1–30).

Biblical authors highly value wine and beer but oppose any abuse. Nevertheless, carousals are frequently mentioned and are often connected with licentiousness. Lot’s two daughters intoxicate their father with wine “and then lie with him” (Genesis 19:32). The author of the book of Ecclesiasticus (also known as Sirach) dissuades a man from sitting with a woman and drinking wine (Ecclesiasticus 9:13). Holofernes wants to dine with Judith and intends to seduce her. When he drinks too much, he falls asleep, and Judith decapitates him (Judith 12–13).

Important figures like Moses, Jesus, and Paul fast at times of particular spiritual, psychological intensity.

### THE STORY OF JUDITH

The story of Judith in the book of Judith exemplifies the meaning the Israelite society accorded to food. The behavior of the two protagonists presupposes their respective fates. Judith, the shining heroine who finally saves the Israelites from the Assyrian siege, always does the right things. She fasts except on religious feasts, she only eats pure food, and she is never drunk. On the other hand Holofernes, the commander in chief of the Assyrian army, is a glutton and drunkard who gives dinner parties every day. This is the starting point for Judith’s project to rescue her people. She goes to Holofernes’s tent dressed in her best clothes and prettily adorned, but she sits at her own table and consumes her own pure food, only pretending to be his guest. Holofernes is blinded by the beauty of the Israelite lady and does not realize she is not truly participating in his party. He eats and drinks until he is so drunk he is incapable of seducing her. When he falls asleep, Judith cuts his head off. Deprived of their leader, the Assyrians withdraw, and Judith is celebrated as the savior of the Israelites.

Moses abstains from eating and drinking for forty days before he climbs up Mount Sinai to bring down the Ten Commandments (Exodus 34:28; Deuteronomy 9:9). These forty days recur in the New Testament when Jesus goes to the desert before he starts to preach (Matthew 4:2–11; Mark 1:12–13; Luke 4:1–13). The Christian interpretation is that everything Jesus says afterward is comparable to Moses' commandments. Paul fasts as a sign of a new beginning after his conversion (Acts 9:9). Whenever the Israelites are at war, they proclaim a general fasting (Judges 20:26; 1 Samuel 14:24–32; 2 Chronicles 20:3; Ezra 8:21–23; Esther 4:15–16; 1 Maccabees 3:46–60). The mourner refuses to eat (Genesis 49:10; Numbers 20:29; 2 Samuel 1:12, 3:35). The preparatory fasting before a religious feast is meant to purify the individual and the community (Leviticus 16:29, 23:26; Numbers 29:7; 2 Kings 25:4–8; Zechariah 7:5, 8:19).

### Preparation of Food

On most biblical occasions it is the women's domain to prepare food. They pound the grains in mortars or use hand mills (Numbers 11:8). From barley they prepare the grits (Leviticus 2:14), sometimes after roasting the barley (Ruth 2:14). They grind the wheat and then bake bread, cake, or biscuits (Genesis 18:6; Leviticus 2:2; 1 Kings 5:2). Bread is leavened or unleavened (Exodus 12:15; Numbers 9:11; Deuteronomy 16:2; Joshua 5:11). Butter and cheese are made from the milk of cows and sheep (Genesis 18:8; 2 Samuel 17:29; Isaiah 7:22). Meat is boiled in a cauldron (1 Samuel 2:13) or roasted on a fire and seasoned with herbs and spices (Exodus 12).

### Meanings of Food in the Biblical Text

Food is integral to communicating the biblical message. Food characterizes situations and persons, and it structures and marks the dramatic development of the text. Metaphors frequently consist of gastronomic terms, and many of Jesus' parables are connected with food. Two important culinary fantasies active in modern texts or imaginations are Cockaigne and cannibalism.

Naming is a simple way to convey something about a person. Biblical figures often have figurative names, many derived from food. Adam, the ancestor of all humankind, is made "from red clay," a soil good for growing certain crops. Adam is described in a close relationship to agriculture, and the moment he leaves paradise he starts farming: "So the Lord God drove him out of the garden of Eden to till the ground from which he had been taken" (Genesis 3:23). Names like Leah, Rachel, Rebecca, Eglah, and Tamar express the qualities of the women bearing them. Leah, which means "cow," and Rachel, which means "mother sheep," become the mothers of the twelve tribes (Genesis 29). Rebecca, "cow," is Isaac's wife and Jacob's mother (Genesis 24, 25, 26). Tamar, "date palm," is the name of a number of influential women from Genesis to Matthew. The women important to Israel are named after animals and plants fundamental to subsistence in the Near East, part of

everyday experience, and available, tame, and reliable. They guarantee survival, and they provide milk, meat, and fruit. In contrast, women and men named after wild animals, often favorite game animals, do not play any important role in the history of Israel. Associated with sexual situations, their names indicate they are beautiful, elegant, charming, and erotic. Examples include Dishon, Ephraim, Tabitha, and Zibiaha, which mean "gazelle"; Hophni, which means "partridge"; and Zipporah, which means "bird" (Genesis 36:21; Exodus 2:16–22; Numbers 12:1; Judges 11:25; 1 Chronicles 1:38; 2 Kings 12:2; Joshua 17:3; Acts 9:36–41).

A person's character is revealed in his or her good behavior at table. A negative figure is usually depicted as lacking good table manners, such as eating and drinking too much, consuming impure food, choosing a wrong seat according to the hierarchy, and general immoderateness. Frequently such people are killed, and their bodies become food for the dogs (1 Kings 14:11, 21:23; Psalms 68:24; Jeremiah 15:3). Good and ideal people eat and drink moderately. They are modest and hospitable, and they carefully choose their food and their company at table.

Feasts and fasts not only structure the year of the community and the life cycles of individuals, they also mark climaxes and happy events, for instance, when people meet after a long separation (Genesis 43:25–34; Luke 15:11–32), on the occasion of a wedding (Genesis 29:22; Judges 14; Matthew 22:1; John 2:1–12), before people part for some time (Genesis 31:54; John 13; Acts 20:7), and when a war is won (Genesis 14:17; 1 Samuel 14:32; Esther 9:17; 1 Maccabees 4:23). Plenty of food and drink is typical of every feast, often indicating that the story is over and everything went well (Judith 16:18–20; Nehemiah 8:10; 2 Maccabees 10:6). Hunger moves people from one place to another, as when Abraham moves to Egypt (Genesis 12:10), when Jacob's family does the same (Genesis 46), and when hunger brings David's pious ancestor Ruth to the family (Ruth). Fasting marks turning points, as when the sterile Hannah prays, fasts, and finally conceives Samuel (1 Samuel 1:7) when the warriors fast before the decisive battle, they will win (Judges 20:26; 2 Chronicles 20:3; Ezra 8:21–23).

The recurrent combination of "milk and honey" can be called a biblical leitmotif and is one of the best-known biblical gastronomic metaphors. Milk and honey are highly valued products, symbols of the wealth of a country. The land God promised to Abraham and his children, usually identified with Canaan, "is a land flowing with milk and honey" (Exodus 3:8, 3:17, 13:5, 33:3; Leviticus 20:24; Numbers 13:27, 14:8; 16:13–14; Deuteronomy 6:3, 11:9, 26:9, 26:15, 27:3, 31:20; Joshua 5:6; Ecclesiasticus [Sirach] 46:8; Jeremiah 11:5, 32:22; Ezekiel 20:6, 20:15). The cup is a metaphor for life or death (Isaiah 51:17–23; Jeremiah 25:15–29, 49:12, 51:7; Ezekiel 23:31–34; Obadiah 16; Habakkuk 2:15–16; Zechariah 12:2; Psalms 16:5, 23:5; Mark 10:38; Matthew 23:25; Revelation 17:4; 1 Corinthians 10:21), and the cup of the

Eucharist is the culminating point in the New Testament (Matthew 26:26–29; Mark 14:22–25; Luke 22:19–20). Psalms 23 is the poetically outstanding citation of the metaphor for the relation between Israel and God, the shepherd and his herd.

Pictures of the other world are deeply rooted in worldly experiences, of which food and eating and drinking are most important. Good and evil, heaven and hell are described with an abundance of excellent food and drink or with hunger, starvation, and cannibalism respectively. The promised land Canaan is expected to produce plenty of food, and paradise is the place without hunger. The Garden of Eden is described in contrast to the place where Adam must work hard to eat his bread (Genesis 2–3). The garden is lost forever, but after death the good will be rewarded. Job states that for the wicked the other world will not “swill down rivers of cream or torrents of honey and curds” (20:17), implying that it will for the good. The New Testament promises all those who believe in Jesus will be invited to the never-ending heavenly feast with Abraham, Isaac, and Jacob or to “the wedding-supper of the Lamb” (Matthew 8:11, 22:2–14, 26:29; Luke 12:37, 13:29, 14:15, 22:16, 22:30; Revelation 3:20, 19:9, 19:17).

If Israel conforms to the commandments, the reward will be fertility and abundance (Leviticus 26:3–13; Deuteronomy 28:1–4). But if the people do not hold the commandments, God will curse them with infertility of the land and the people (Leviticus 26:20–39; Deuteronomy 28), thistles and thorns will grow instead of corn [wheat, not maize] and fruit in the fields (Genesis 3:18; Job 31:40; Wisdom 24:31; Isaiah 5:6, 32:13; Jeremiah 12:13; Hebrews 6:8). People will be driven to eat unclean food (2 Kings 6:25; 2 Maccabees 6:18–20, 7:1; Isaiah 65:4, 66:3, 66:17; Ezekiel 4:9; Daniel 1:8), they will suffer from hunger and will starve to death (Deuteronomy 28:48, 32:24; 2 Samuel 24:13; 1 Chronicles 21:12; Psalms 34:11, 105:16; Isaiah 32:6; Jeremiah 11:22, 42:16; Luke 6:25; Revelation 18:8), and worst of all they will eat their own children (Leviticus 26:27–29; Deuteronomy 28:53–57; Lamentations 4:10; Zechariah 11:9). Eating one's own children on the one hand is the worst of sins and on the other hand is the strongest punishment for sinning. Eating the children is the reversal of giving birth. Instead of propagating humankind and the family, society is endangered. If people do this willingly, they violate God's wish to have a great number of followers, but if they violate his commandments, he will end their existence. To be without children means to be without a future, the name of the family extinguished forever. Living on in Israel means living on in future generations, as the many genealogies show (Genesis 4:20, 10:21, 17:4–16, 19:30–38, 25:12–18, 36:9; Exodus 1:5; Ruth 4:18–22; 1 Chronicles 2–8; Matthew 1:1–17).

**BIOACTIVE FOOD COMPONENTS.** The term “bioactive food component” refers to nonessential biomolecules that are present in foods and exhibit the capacity to modulate one or more metabolic processes, which results in the promotion of better health. Bioactive food components are usually found in multiple forms such as glycosylated, esterified, thiolated, or hydroxylated. Bioactive food components also have multiple metabolic activities allowing for beneficial effects in several diseases and target tissues. In general, it is thought that bioactive food components are predominantly found in plant foods such as whole grains, fruit, and vegetables. However, probiotics, conjugated linolenic acid, long-chain omega-3 polyunsaturated fatty acid, and bioactive peptides are most commonly found in animal products such as milk, fermented milk products and cold-water fish.

Table 1 summarizes the biological function and food sources for both plant- and animal-based bioactive food components. However, a review of both plant- and animal-based bioactive food components is beyond the scope of this article. Therefore, this article will focus on plant-based bioactive food components.

## Common Forms Found in Foods

There are myriad bioactive food components in plant-based foods. A partial list includes the polyphenols, phytosterols, carotenoids, tocopherols, tocotrienols,

organosulfur compounds including isothiocyanates and diallyl- (di, tri)sulfide compounds, soluble and insoluble fiber, and fructo-oligosaccharide. It is most common to find mixtures of these compounds within a plant food rarely is one class of bioactive food component found singly.

Polyphenols are the most numerous and widely distributed group of bioactive molecules. Polyphenols are a diverse group of plant substances that contain one or more benzene rings and varying number of hydroxyl (OH), carbonyl (C=O), and carboxylic acid (COOH) groups. These commonly exist with one or more attached sugar residues (that is, conjugated). The most common class of polyphenols is the flavonoids. Other types of polyphenols include catechins, thearubingens, theaflavins, isoflavones, and over eight thousand others. Food sources of polyphenols and flavonoids include vegetables, fruits, cereals, legumes, nuts, tea, wine and other beverages made with fruit, vegetables, and grains. The polyphenol content can vary tremendously between food sources and within foods of the same type. For example, Bravo (1998) reported the following ranges for total polyphenols in barley and millet as 590 to 1,500 mg/100 g dry matter, 8.7 to 30.9 mg/100 g dry matter for oats and corn, 20 to 2,025 mg/g fresh onions and leeks, and 6 to 15 mg/100 g fresh brussels sprouts. For blueberries, strawberries, cranberries, and raspberries the total polyphenol content is 37 to 429 mg/100 g berries.

The organosulfur compounds are commonly found in cruciferous vegetables such as broccoli, cauliflower, and brussels sprouts or allium vegetables such as garlic, leeks, and onions. Organosulfur compounds contain sulfur atoms that are bound to a cyanate group or a carbon atom in a cyclic or noncyclic configuration. The bioactive components of foods containing organosulfur compounds are obtained only after cutting, chewing, or crushing has damaged the vegetable. In cruciferous vegetables various isothiocyanates such as sulforaphane, phenethyl-isothiocyanate, and benzyl isothiocyanate are formed from glucosinolates by the action of myrosinase. In alliums, allicin is formed from alliin and then rapidly converted to diallyl sulfide, diallyl disulfide or diallyl trisulfide by the action of allinase. In both cruciferous and allium vegetables, these hydrolytic breakdown products are the health-promoting bioactive food components.

Phytosterols are the plant counterparts of cholesterol in animals. The structures are similar, however; the side-chain in plant sterols contains additional double bonds and methyl and/or ethyl groups. The most common bioactive phytosterols are beta-sitosterol, campesterol, and stigmasterol. The nonvegetarian diet contains approximately 250 mg/day of unsaturated phytosterols while a vegetarian diet contains over 500 mg/day. The best food sources include nuts, seeds, unrefined plant oils, and legumes. The saturated derivatives of plant sterols are plant stanols, the most common being sitostanol. Plant stanols occur naturally in wood pulp, tall oil, and

soybean oil, but are most commonly obtained in the diet by chemical hydrogenation of plant sterols. Western diets contain approximately 20 to 50 milligrams of plant stanols.

The carotenoids are lipid-soluble plant pigments that are either oxygenated or non-oxygenated hydrocarbon containing at least forty carbons and an extensive conjugated double bond system. Beta-carotene, alpha-carotene, and lycopene are the predominant nonpolar bioactive carotenoids and lutein is the primary polar bioactive carotenoid. Carotenoids can be found esterified to fatty acids or unesterified in plant tissue. Carrots, squash, sweet potato, and spinach are abundant in both beta- and alpha-carotene and the dark green leafy vegetables such as kale, spinach, mustard greens, and green beans are good sources of lutein. Lycopene is found predominantly in tomatoes. The total carotenoid content of fruits and vegetables varies with age and storage (Parker).

The tocopherols and tocotrienols are lipid-soluble bioactive compounds that contain a phenolic-chromanol ring linked to an isoprenoid side chain that is either saturated (tocopherols) or unsaturated (tocotrienols). There are also four primary forms of tocopherols and tocotrienols—alpha, beta, gamma, and delta—that differ in the number and position of methyl groups on the phenolic-chromanol ring. In addition, the tocopherols have three asymmetrical carbons at position 2, 4', and 8' of the isoprenoid side chain. Consequently, there are eight isomeric forms of tocopherols, of which RRR- $\alpha$ -tocopherol has the greatest bioactivity and is also the most abundant in human blood and tissues. Typical dietary sources of both tocopherol and tocotrienols include vegetable oils; nuts and the germ portion of grains are rich sources of both these compounds.

### Biological Actions

There is a significant lack of understanding of the precise biological mechanism(s) of how plant-based bioactive food components impart health-promoting benefits. It is clear that bioactive food components act simultaneously at different or identical target sites. Bioactive food components have been shown to have the potential to reduce the risk of cancer, cardiovascular disease, osteoporosis, inflammation, type 2 diabetes, and other chronic degenerative diseases.

Bioactive food components have health-promoting roles at various stages of diseases that are associated with multiple progressive steps, from initiation to development. For example, in cardiovascular disease, isoflavones may reduce circulating oxidized low-density lipoproteins in the plasma, bind cholesterol in the intestinal tract thereby reducing absorption of dietary cholesterol, enhance bile excretion thereby reducing endogenous cholesterol levels, and modulate arterial elasticity thereby improving blood vessel dilation and constriction response.

As antioxidants, polyphenols, carotenoids, tocopherols, and allyl sulfides quench free radicals and reactive

oxygen species. A free radical is a carbon or oxygen atom that has an unpaired electron and is highly unstable. Free radicals can form in lipids, proteins, and carbohydrates. The primary actions of antioxidants include the regulation of the redox potential within a cell and the reduction of potential initiators of carcinogenesis. The redox potential refers to the balance of the reducing and oxidizing reactions that occur within the cell. Redox changes within a cell are able to trigger various molecular responses such as induction of apoptosis (cell death) and activation of signal transduction (the transfer of messages between cells and within a cell). Therefore, redox and antioxidant regulation of physiological and pathological processes is important in optimizing health and disease prevention.

Other bioactive compounds are able to bind to toxins or carcinogens in the intestinal tract thereby preventing transformation or even absorption such as the binding of *N*-nitroso compounds in the intestinal tract by polyphenols in tea. The lipid-lowering mechanism of dietary fiber and phytosterol/stanols occurs by sequestering cholesterol in the intestinal tract and reducing cholesterol absorption. Dietary fiber is the indigestible parts of plant foods; it provides structure to the plant cell walls and is composed of long straight chains of carbohydrate molecules held together by bonds that cannot be broken by human digestive enzymes. This long fibrous structure allows dietary fibers to entrap harmful toxins and carcinogens in the digestive tract. There are two types of dietary fiber: soluble and insoluble. Soluble dietary fiber can dissolve in or absorb water and is effective in binding toxins and cholesterol in the intestinal tract. Insoluble dietary fiber, on the other hand, cannot dissolve in water and is effective in adding bulk and increasing the rate of passage of food through the intestinal tract. Insoluble dietary fiber, therefore, acts by diluting out potential carcinogens and decreasing contact of toxins and carcinogens with the intestinal tract by speeding their passage out of the body. Foods rich in soluble dietary fiber include apples, cranberries, mango, oranges, asparagus, broccoli, carrots, peanuts, walnuts, most legumes, oats, and psyllium. Rich food sources of insoluble dietary fiber include apples, bananas, berries, broccoli, green peppers, spinach, almonds, sesame seeds, most legumes, brown rice, whole-wheat breads, and cereals.

The structural similarity between several isoflavone metabolites and the metabolite of estrogen, estradiol, suggests the possibility of estrogen-like biological activities. Isoflavones or phytoestrogens, however, exhibit antagonist estrogen activity resulting in lower overall exposure to estrogen in premenopausal women and reducing breast cancer risk (Cassidy et al. 1994, 1995; Shimizu et al.). In postmenopausal women phytoestrogen-rich diets reduce the hormone-sensitive increases in plasma cholesterol levels and bone loss (Potter et al.; Setchell and Cassidy).

The induction of enzyme systems that detoxify toxic chemicals such as the phase I and phase II detoxifying

enzymes is thought to reduce one's susceptibility to mutagenic effects. Bioactive food components with antioxidant functions are able to activate phase II detoxifying enzymes via an antioxidant-responsive element (Mukhtar and Ahmad). Isothiocyanates, in particular sulforaphane, are potent mono-inducers of phase II detoxifying enzymes (Zhang et al.). Diallyl sulfides from garlic preparations, on the other hand, are inducers of both phase I and phase II detoxifying enzymes (Yang et al.).

A primary mechanism for immune-modulation is the multiple antioxidant capability of polyphenols, tocopherols, carotenoids, isothiocyanates, and allyl sulfides. Together these compounds are able to reduce the deleterious effects of reactive oxygen species and free radicals, which cause premature death of immune cells (Brennan et al.). Bioactive food components have also been shown to stimulate the phagocytic action of macrophages and synthesis of several immune cell types, which increases the protection against infection. Among the foods that have been shown to have beneficial immuno-modulatory effects are broccoli, garlic, onions, vegetable oils, almonds, walnuts, and others that are listed in Table 1.

### Effects of Food Processing

In general, processing of fresh fruits and vegetables results in changes in composition of the bioactive food components. These changes can be beneficial or detrimental to the total content of health-promoting phytochemicals. It has been shown that coarseness of cutting, length of storage post-harvest, steam blanching, and thermal processing all influence the retention of bioactive compounds in cruciferae and allium vegetables (Howard et al.; Song and Milner). Reported losses of 30 percent to 80 percent of bioactive isothiocyanates have been reported (Howard et al.). Temperatures of 212°F (100°C) and higher result in the inactivation of key enzymes, myrosinase in cruciferae and allinase in allium vegetables, thereby reducing the amount of bioactive components. However, temperatures associated with normal cooking have shown little evidence of substantial loss of isothiocyanates. Leaching of glucosinolates and hydrolysis products also results in a reduction in total phytochemical content following cooking. Research has shown that heating garlic to a temperature of 140 to 212°F (60 to 100°C) or microwave heating for 30 to 60 seconds results in significant losses of the anti-inflammatory, anticancer, antimicrobial, and antioxidative activities of garlic (Song and Milner). However, the protective effect of garlic was nearly restored if the garlic preparation was allowed to sit for 10 minutes at room temperature prior to any heat treatment.

The bioavailability of carotenoids and other lipid-soluble bioactive food components has been shown to be improved with processing that increases surface area, such as cutting and chopping, and heat treatments that break down the protein and carbohydrate matrix that bind carotenoids (Stahl and Sies; Parker). The brewing

TABLE 1

**Summary listing of various bioactive food components, common food sources, and biological functions**

Bioactive component	Food source	Function
Glucosinolates, diallyl sulfides, isothiocyanates	Broccoli, cauliflower, brussels sprouts, garlic, onions	Induction of detoxifying enzyme systems, antimicrobial, immunomodulator, anticancer
Tocopherols and tocotrienols	Vegetable oil, nuts, seeds	Antioxidant, immunomodulator
Isoflavonoids and polyphenols	Grapes, red wine, tea, fresh fruit, and vegetables	Antioxidant, lipid-lowering, immunomodulator, antiosteoporotic, anticancer
Phytoestrogens (genistein, daidzein)	Soybean and other soy-based products, flaxseed, cabbage, legumes, tea	Antiestrogen, anti-osteoporotic, antiproliferative
Phytosterols	Vegetable oils, nuts	Lipid-lowering
Dietary fiber	Whole grains, oats, fresh fruit with skin	Lipid-lowering
$\gamma$ -linolenic acid, $\alpha$ -linolenic acid, and omega-3 fatty acids	Evening primrose or borage oil, walnuts, rapeseed, flaxseed, fish, microalgae	Anti-inflammatory, lipid-lowering
Lutein	Green leafy vegetables	Reduction in age-related macular degeneration
Carotenoids	Carrots, corn, squash, green leafy vegetables, oranges, papaya, red palm oil	Antioxidant immunomodulators
Lycopene	Tomatoes	Antiproliferative, anticancer
Bioactive peptides: lactoferrin, glycomacropeptide	Milk and fermented milk products	Immune system enhancing, antiproliferative, antimicrobial
Probiotics	Fermented milk products	Immunomodulators, anticancer, gastrointestinal health modulators

of tea leaves, whether black or green, releases 69 to 85 percent of bioactive flavonoids within 3 to 5 minutes in hot water (Trevisanato and Kim).

### Dietary Recommendations

Clearly, bioactive food components will play an important role in health maintenance in the future. However, information is needed in regards to the bioavailability of bioactive food components and the effective dosage required in humans to optimize health benefits. Current information suggests that to obtain and maintain blood levels of beneficial polyphenols, especially phytoestrogens and isoflavonoids, and carotenoids one needs to consume on a daily basis 25 to 60 grams of soy protein,

five to nine servings of fruits and vegetables, one fresh clove of garlic, and four to six cups of green or black tea (Klotzbach-Shimomura). To achieve optimal phyto-sterol/stanol and fiber levels a daily intake of 25 to 35 grams of fiber is recommended by consuming seven to eleven servings of whole grains, legumes, pastas or nuts, and five to nine servings of fruits and vegetables.

The average American diet consists of two to four servings of fruits and vegetables and only five to seven servings of whole grains. Consequently, there is still a need to provide information and food choices to consumers to aid in the selection of a diet that contains optimal levels of health-promoting bioactive food components.

Joy Emilie Swanson

**BIODIVERSITY AND THE CORNUCOPIA OF FOODS.** Whenever you take up a bowl of paella, or a salad plate of mixed greens, nuts, and fruits, you are enjoying the benefits of biodiversity. There is something intrinsically pleasurable about a heterogeneity of vegetable varieties, shellfish species, or the ecological mosaic of marine and terrestrial landscapes sampled to prepare such dishes. Biodiversity can be simply defined as the "variety of life on Earth," and it includes both the richness of habitats found within different regions as well as the richness of species, varieties, and genes.

In a world where agricultural and aquacultural practices correspond to the growth rates and population densities of edible plants and animals, biodiversity can be sustained, without depleting harvests or degrading ecological habitats. But where traditional practices of food production and harvesting have been displaced, or species-rich landscapes have been degraded or converted to urban or industrial uses, this diversity is imperiled. In other words, the continued availability of this cornucopia of foods can no longer be taken for granted, and the term "biodiversity" is increasingly used in the context of loss of biodiversity or the extinction crisis. The number of species doomed to extinction each year of this coming

Biodiversity is evident in the large range of grass and flower species occupying this prairie at the National Bison Refuge in Montana. © PHOTO RESEARCHERS, INC.

Biodiversity includes not just the mix of different species but also the unique variations within species, as in the case of these heirloom turnips. The flat-rooted variety is Purple Top Milan, the white one in the center Goose Egg, and the ones beneath it Orange Jelly. Each variety also exhibits a very different flavor and storage qualities. PHOTO BY L. WILBUR ZIMMERMAN. COURTESY OF THE ROUGH-WOOD SEED COLLECTION.

century is projected by Harvard professor E. O. Wilson to be on the order of 27,000 unique and irreplaceable life forms. This extinction rate is the highest rate since humankind began manipulating life on earth.

Although the term “biodiversity” first came into vogue around 1988, during a conference on this theme sponsored by the National Academy of Sciences of the United States, synonyms such as “biological diversity” and “biotic diversity” had already been in currency among scientists and conservationists for some four decades. However, most people erroneously equated the term with species diversity or species richness, as if the number of plant and animal species in a given area served as the only indicator of biodiversity. “Biodiversity” is now considered to include the variety of life considered at all levels, from genetic variants belonging to the same species, through arrays of species and lifeforms, to the variety of habitats and ecosystems found within an ecological landscape including both wildlands and farmlands.

Let us first consider how our cornucopia of foods is filled with the genetic variation found within a single species. Consider, for example, the astonishing variety of vegetables and fruits grown and stored on just one patch of land, such as that of the Heritage Farm of the Seed Savers Exchange in Decorah, Iowa. The dozen or so members of the Seed Savers Exchange staff grow and maintain the genetic diversity represented by some 4,100

named varieties of tomatoes (one species), 3,600 varieties of beans (six species), 1,000 varieties of peas (one species), 1,200 chili peppers (four species), 1,200 squash and pumpkin varieties (four species), 400 melons (two species), 650 varieties of maize (two species), and 200 varieties of garlic (one species). Each of these varieties, whether it is a land race developed exclusively by traditional farmers and gardeners, or a cultivar developed by scientifically trained plant breeders, has been selected for its unique flavor, texture, color, size, shape, keeping time, as well as for its maturation rates, productivity, and resistance to pests, diseases, droughts, and freezes.

Unfortunately, many varieties such as these have already been lost from future use by gardeners, chefs, brewers, and the public at large. For example, it is estimated that 60 percent of the crop land races grown by indigenous tribes in North America at the time of first European colonization have been lost over the following five centuries. Several threats have led to losses of genetic replacement by modern commercial cultivars, and genetic contamination through accidental hybridization with modern cultivars, including genetically modified organisms (GMOs). Further consequences include genetic erosion due to the decline in traditional farming, along with reductions in planting areas and crop population sizes, and genetic extirpation resulting from the genocide or displacement of traditional farming communities, and termination of their agricultural practices.

## REGULATORY OVERSIGHT

Three government agencies monitor the development and testing of biotechnology crops: the Food and Drug Administration (FDA), the U.S. Department of Agriculture (USDA), and the Environmental Protection Agency (EPA). These agencies work together to ensure that biotechnology foods are safe to eat, safe to grow, and safe for the environment.

**U.S. Food and Drug Administration (FDA):** Lead agency in assessing safety for human consumption of plants or foods that have been altered using biotechnology, including foods that have improved nutritional profiles, food quality, or food processing advantages.

**U.S. Department of Agriculture:** Provides regulatory oversight to ensure that new plant varieties pose no harm to production agriculture or to the environment. USDA's Animal and Plant Health Inspection Service (APHIS) governs the field testing of biotechnology crops to determine how transgenic varieties perform relative to conventional varieties, and the balance between risk and reward.

**Environmental Protection Agency (EPA):** EPA provides regulatory and safety oversight for new plant varieties, such as insect-protected biotechnology crops. EPA regulates any pesticide that may be present in food to provide a high margin of safety for consumers.

In addition to genetic variation below the species level, biodiversity is influenced by the number of crop species grown in a given area and how they are intercropped. For example, some fifty botanical species of fruits, vegetables, and nuts can be found in some indigenous dooryard gardens, intermixed in what agroecologists term “polycultures.” These crop mixtures often outyield the harvests that a single crop would produce on the same area of land, and harbor a variety of beneficial insects, such as predators on pests and pollinators.

At the landscape level, an ecological mosaic of fields, gardens, orchards, hedgerows, and managed wildlands provides what is now termed “agrobiodiversity,” which includes habitat for both wild and domesticated organisms. It is at this level that land conservation organizations interested in protecting the diversity of foods desired by the public must succeed, for this diversity can be easily lost without the cultural landscapes that sustain species, their interactions with one another, and traditional ecological knowledge about how to manage them.

*Gary Paul Nabhan*

**BIODYNAMIC GARDENING.** *See Organic Agriculture; Organic Farming and Gardening.*

**BIOTECHNOLOGY.** Biotechnology, in its broadest sense, is the use of biological systems to carry out technical processes. Food biotechnology uses genetic methods to enhance food properties and to improve production, and in particular uses direct (rather than random) strategies to modify genes that are responsible for traits such as a vegetable's nutritional content. Using modern biotechnology, scientists can move genes for valuable traits from one plant into another plant. This way, they can make a plant taste or look better, be more nutritious, protect itself from insects, produce more food, or survive and prosper in inhospitable environments, for example, by incorporating tolerance to increased soil salinity. Simply put, food biotechnology is the practice of directing genetic changes in organisms that produce food in order to make a better product.

In nature, plants produce their own chemical defenses to ward off disease and insects thereby reducing the need for insecticide sprays. Biotechnology is often used to enhance these defenses. Some improvements are crop specific. For example, potatoes with a higher starch content will absorb less oil when frying, and tomatoes with delayed ripening qualities will have improved taste and freshness.

### **Paving the Way to Modern Biotechnology**

Advances in science over many years account for what we know and are able to accomplish with modern biotechnology and food production. A brief review of genetics

and biochemistry is useful in evaluating the role of biotechnology in our food supply.

Proteins are composed of various combinations of amino acids. They are essential for life—both for an organism's structure, and for the metabolic reactions necessary for the organism to function. The number, kind, and order of amino acids in a specific protein determine its properties. Deoxyribonucleic acid (DNA), which is present in all the cells of all organisms, contains the information needed for cells to put amino acids in the correct order. In other words, DNA contains the genetic blueprint determining how cells in all living organisms store, duplicate, and pass information about protein structure from generation to generation.

In 1953 James Watson and Francis Crick published their discovery that the molecular structure of DNA is a double helix, for which they, along with Maurice H. F. Wilkins, won a Nobel Prize in 1962. Two strands of DNA are composed of pairs of chemicals—adenine (A) and thymine (T); and guanine (G) and cytosine (C). A segment of DNA that encodes enough information to

## GENETICALLY MODIFIED ORGANISMS: HEALTH AND ENVIRONMENTAL CONCERNS

There is really little doubt that, at least in principle, the development of genetically modified organisms (GMOs) can offer many advantages. Genetically modified organisms have included crops that are largely of benefit to farmers and not clearly of broad public value. Plans for development of GMOs include foods that have far greater nutritional and even pharmaceutical benefit; crops that can grow in regions that currently cannot provide enough food for subsistence; and foods that are more desirable in terms of traits that the public wants. The market forces that largely determine which products are developed are complicated, and there are important trade-offs: the traits that may be needed to feed a starving world are different from the traits farmers in the United States want, and both may differ from the characteristics the paying public supports.

Most criticisms of genetic engineering focus on food safety and environmental impacts. What impact will GMOs have on the health of those who eat them? Will some individuals develop allergic reactions? The new technology makes it possible to cross species barriers with impunity. A scare over StarLink corn is instructive of this kind of problem. “*Bt* corn,” a common GMO, includes a gene from *Bacillus thuringiensis*, which produces a pesticide that kills the European corn borer. StarLink is a variety of *Bt* corn that includes a protein (Cry9C) that does not break down as easily in the body, which increases the risk of allergic reactions in some people

(though there are no verified cases of this). StarLink corn was approved for animal feed but not for human consumption. Unfortunately it is difficult if not impossible to keep the food supply for animals and humans separate. The result has been the discovery of small amounts of StarLink corn throughout the food supply. (Of course, there is also the question whether a small trace of Cry9C in a fast-food taco is the greatest health problem involved in such a meal.)

A second set of concerns arises over the environmental impact of GMOs. There are several different concerns. First, there are worries about gene flow. The same genes that may one day make it possible for plants to grow in poor, salty soil or in relatively arid regions could create an ecological nightmare by allowing these crops to spread beyond their normal range as a result of the gene(s) that have been transferred into the crop itself, or if those same genes should be introduced to other plants. This can happen through outcrossing between the GMOs and closely related plants. For example, GM wheat could cross with native grasses in South America to alter the makeup of the ecosystem and potentially create “super weeds,” a possibility that has raised concerns in the “Wheat Belt” of the United States and elsewhere. Even in the absence of gene flow, the GMOs themselves could become super weeds (or the animal equivalent) as a result of the traits that make them better suited to new habitats. The environmental trade-off for technology that

make one protein is called a gene. It is the order of DNA’s base pairs that determines specific genes that code for specific proteins, which determines individual traits.

By 1973 scientists had found ways to isolate individual genes, and by the 1980s, scientists could transfer single genes from one organism to another. This process, much like traditional crossbreeding, allows transferred traits to pass to future generations of the recipient organism.

### One Goal, Two Approaches

The objective of plant biotechnology and traditional crop breeding is the same: to improve the characteristics of seed so that the resulting plants have new, desirable traits. The primary difference between the two techniques is how the objective is achieved. Plant breeders have used traditional tools such as hybridization and crossbreeding to improve the quality and yield of their crops with a resulting wide variability in our foods. These traditional techniques resulted in several benefits, such as greatly in-

creased crop production and improved quality of food and feed crops, which has proven beneficial to growers and producers as well as consumers through a reduction of the cost of food for consumers. However, traditional plant breeding techniques do have some limits; only plants from the same or similar species can be interbred. Because of this, the sources for potential desirable traits are finite. In addition, the process of crossbreeding is very time-consuming, at times taking ten to twelve years to achieve the desired goal—and complications can arise because all genes of the two “parent” plants are combined together. This means that both the desirable *and* undesirable traits may be expressed in the new plant. It takes a significant amount of time to remove the unwanted traits by “back crossing” the new plant over many generations to achieve the desired traits. These biotech methods can preserve the unique genetic composition of some crops while allowing the addition or incorporation of specific genetic traits, such as resistance to disease. However, development of transgenic crop varieties still requires a significant investment of time and resources.

makes it possible to produce sustainable agriculture or aquaculture in regions where it cannot “naturally” flourish is the significant risk of loss of biodiversity and the unchecked spread of plants or animals into unintended regions. (The argument is made, however, that biotechnology can be used to increase yields on the land that is currently used for agricultural production, allowing nonfarm land to be retained as forests and reserves and thereby conserve biodiversity.)

In addition to these concerns over the ecosystem and the creation of superweeds, there is a worry over the potential impact of some GMOs on nontarget organisms. Cornell University researchers found that pollen from *Bt* corn could kill the larvae of monarch butterflies that ingested it. This raised the fear that these engineered crops could kill butterflies and other nontarget organisms in addition to the corn borer. The consensus from subsequent field research is that *Bt* corn does not pose a major threat to monarch butterfly populations—loss of habitat in Mexico, where the butterflies overwinter, is a more serious threat. Nevertheless, the *Bt* corn–butterfly issue showed that it is not always possible to predict the consequences that may arise from the introduction of these crops.

Genetically engineered microorganisms present even greater environmental and health concerns. It will soon be possible to engineer bacteria and viruses to produce deadly pathogens. This could well open a new era in biological weapons in addition to the environmental problems that could result from the release of organisms into the environment. The environmental assessment of

the widespread introduction of engineered microorganisms has only barely begun to receive attention (Cho et al., 1999).

These concerns are exacerbated by some inadequacies in the regulatory framework for GMOs. There is a growing sense that the Food and Drug Administration, the U.S. Department of Agriculture, and the Environmental Protection Agency are not sufficiently rigorous or consistent in how they regulate GMOs and that there should be a single set of standards, including a mandatory environmental assessment. The opposition to GMOs in Europe is much more widespread than in the United States, and the single most important factor for the differences between European and American attitudes is the level of confidence in the regulatory institutions that protect the food supply. After “mad cow disease,” Europeans do not trust their governments to provide safe food. A similar loss in confidence among U.S. consumers could have a similar effect. In spite of these concerns, however, there have so far been no documented food safety problems resulting from the introduction of GM crops in the mid-1990s and their large-scale consumption by the American public. There have also been no ecological disasters, although the time since their introduction has been too brief for the absence of disaster to be very meaningful. In some crops, notably in *Bt* cotton, there have been significant reductions in the use of pesticides.

### The Many Applications of Biotechnology

Since the earliest times, people have been using simple forms of biotechnology to improve their food supply, long before the discovery of the structure of DNA by Watson and Crick. For example, grapes and grains were modified through fermentation with microorganisms and used to make wine, beer, and leavened bread. Modern biotechnology, which uses the latest molecular biology technology, allows us to more directly modify our foods. Whereas traditional plant breeding mixes tens of thousands of genes, biotechnology allows for the transfer of a single gene, or a few select genes or traits. The most common uses thus far have been the introduction of traits that help farmers simplify crop production, reduce pesticide use in some crops, and increase profitability by reduction of crop losses to weeds, insect damage, or disease.

In general, the early applications of crop biotechnology have been at points in our food supply chain where economic benefit can be gained. The following are ex-

amples of modern biotechnology where success has been achieved or is in progress.

**Insect resistance.** Crop losses from insect pests can cause devastating financial loss for growers and starvation in developing countries. In the United States and Europe, thousands of tons of pesticides are used to control insects. Using modern biotechnology, scientists and farmers have removed the need for the use of some of these chemicals. Insect-protected plants are developed by introducing a gene into a plant that produces a specific protein from a naturally occurring soil organism. *Bacillus thuringiensis* (*Bt*) is one of many bacteria naturally present in soil. This bacterium is known to be lethal to certain classes of insects, and only those organisms. The *Bt* protein produced by the bacterium is the natural insecticide. Growing foods, such as *Bt* corn, can help eliminate the application of chemical pesticides and reduce the cost of bringing a crop to market. The introduction of insect-protected crops such as *Bt* cotton has allowed reduced use of chemical pesticides. This suggests that

genetically engineered food crops can also be grown with reduced use of pesticides, a development that would be welcomed by the general public.

**Herbicide tolerance.** Every year, farmers must battle weeds that compete with their crops for water, nutrients, sunlight, and space. Weeds can also harbor insects and disease. Farmers routinely use two or more different chemicals on a crop to remove both grass and broadleaf weeds. In recent years new “broad-spectrum” chemicals have been discovered that control all these weeds and therefore require only one application of one chemical to the crop. To provide crops with a defense against these nonselective herbicides, genes have been added to plants that render the chemicals inactive—but only in the new, herbicide-resistant crop. Many benefits come from these crops, including better and more flexible weed control for farmers, increased use of conservation tillage (involving less working of the soil and thereby decreasing erosion), and promoting the use of herbicides that have a better environmental profile (that is, that are less toxic to nontarget organisms).

**Disease resistance.** Many viruses, fungi, and bacteria can cause plant diseases, resulting in crop damage and loss. Researchers have had great success in developing crops that are protected from certain types of plant viruses by introducing DNA from the virus into the plant. In essence, the plants are “vaccinated” against specific diseases. Because most plant viruses are spread by insects, farmers can use fewer insecticides and still have healthy crops and high yields.

**Drought tolerance and salinity tolerance.** As the world population grows and industrial demand for water supplies increases, the amount of water used to irrigate crops will become more expensive or unavailable. Creating plants that can withstand long periods of drought or high salt content in soil and groundwater will help overcome these limitations. Although genetically engineered crops with enhanced drought tolerance are not yet commercially available, significant research advances are pointing the way to creating these in the future.

**Food applications.** Research into applications of biotechnology to food production covers a broad range of possibilities. Examples of food applications also include increasing the nutrient content of foods where deficiencies are widespread in the population. For example, researchers have successfully increased the amount of iron and beta-carotene (the precursor to vitamin A in humans) in carrots and “golden rice”—a biotech rice developed by the Rockefeller Foundation that may help provide children in developing nations with the vitamin A they need to reduce the risk of vision problems or blindness.

Another example of food biotechnology is crops modified for higher monounsaturated fatty acid levels in the vegetable to make them more “heart-healthy.” Efforts are also under way to slow the ripening of some crops, such as bananas, tomatoes, peppers, and tropical

fruits, to allow time to ship them from farms to large cities while preserving taste and freshness.

Other possible food applications for which pioneering research is under way include grains and nuts where naturally occurring allergens have been reduced or eliminated. Potatoes with higher starch content also promise to have the added potential to reduce the fat content in fried potato products, such as french fries and potato chips. This is because the starch replaces water in the potatoes, causing less fat to be absorbed into the potato when it is fried.

**Edible vaccines.** Vaccines that are commonly used today are often costly to produce and require cold storage conditions when shipped from their point of manufacture in the developed world to points of use in the developing world. Research has shown that protein-based vaccines can be designed into edible plants so that simple eating of the material leads to oral immunization. This technology will allow local production of vaccines in developing countries, reduction of vaccine costs, and promotion of global immunization programs to prevent infectious diseases.

**Global food needs.** The world population has topped six billion people and is predicted to double by 2050. Ensuring an adequate food supply for this booming population is going to be a major challenge in the years to come. Biotechnology can play a critical role in helping to meet the growing need for high-quality food produced in more sustainable ways.

### What Are Consumers Saying?

Crops modified by biotechnology (also known as genetically modified or GM crops) have been the subjects of public discussion in recent years. Considerable public discussion may be attributed to the public’s interest in the safety and usefulness of new products. Although biotechnology has a strongly supported safety record, some groups and organizations abroad and in the United States have expressed a desire for stronger regulation of biotechnology-derived products than of similar foods derived from older technology. The assessment of the need for new regulation is related to an understanding of the science itself, as was detailed in the sections above; this is a continual process of development.

Consumer acceptance is critical to the success of biotechnology around the world. Attitudes toward biotechnology vary from country to country because of cultural and political differences, in addition to many other influences.

In the United States, the majority of consumers are supportive about the potential benefits biotechnology can bring. Generally, U.S. consumers feel they would like to learn more about the topic, and respond favorably when they are given accurate, science-based information on the subject of food biotechnology.

**BIRDSEYE, CLARENCE.** Clarence "Bob" Birdseye (1886–1956), American businessman and inventor, was originally an Amherst biology major, but dropped out and became a U.S. field naturalist in Labrador in 1920. There he became impressed with the well-

preserved cellular structure of cooked fish that was frozen naturally in the Arctic outdoors. He noted that this quick freezing process caused less crystallization within the fish tissue. Once he returned to the United States, Birdseye developed his crude Multiplate Quick Freeze Machine: tightly sealed cartons, encased in metal, that were filled with food and then lowered into a low-temperature brine solution that froze the foods. Later, he froze foods with calcium chloride brine chilled to  $-40^{\circ}\text{F}$ . In 1924 he organized the General Seafood Corporation and turned his attention to developing refrigerated railroad boxcars to transport frozen foods nationwide. In 1929 Birdseye sold his company to Postum, Inc., which became General Foods Corporation. His line of frozen foods was renamed Birds Eye.<sup>TM</sup> Ultimately, in 1949, using the anhydrous freezing process, Birdseye managed to cut freezing time from 18 hours to 90 minutes.

Though his process was not the first to freeze foods, distinction came to him for the quickness of his method for producing tasty, well-preserved fresh fish, fruits, and vegetables in retail-sized containers. The restaurant business profited greatly from his work. Birdseye held three hundred patents, in addition to a patent for a process of converting crushed sugarcane residue into paper pulp.

#### FROZEN PEAS

Birdseye's process indirectly improved the diet of the industrialized world by making possible the freshest frozen foods, frozen at or near farm sites, year round. This later led to the packaging of ethnic foods and meal combinations such as TV dinners. One of his most popular frozen products is green peas, the second largest vegetable crop in the United States. In the early twenty-first century more than 90 percent of all peas are sold as frozen peas. Frozen peas retain their brightest color and original shapes when placed in boiling water and removed from the heat.

Marty Martindale

**BIRTHDAY FOODS.** Food is almost always a significant part of the observance or celebration of a birthday in the Western world. It may play several roles: as refreshments for those attending a celebration; as a gift, such as a box of candy for the honoree; as sweets or cupcakes taken to school by the birthday child; or the candy in a piñata at a party. Families often have their own favorite festive food that is served on birthdays of family members, or a favorite food of the birthday celebrant will be served in his or her honor.

In some cultures, a birthday food is an important cultural symbol recognized by the entire community. Wheat noodles, a symbol of longevity, are stretched to great lengths and served in soup to birthday celebrants in Northern China. Another symbol of longevity there, the peach, appears for birthdays as a bun, shaped and colored like a peach, with a sweet paste filling.

Food may be offered to the gods as a part of the religious celebration of a birthday. In Thai communities it is taken to the temple on the birthday morning, to receive a birthday blessing from a monk. In Sri Lanka, children go to the temple on their birthdays to receive a special blessing and to give money to the priest for a special offering of a traditional food, such as rice porridge, to the gods. This is also shared with the family.

Other traditional festive foods include the French *croquembouche*, a cone-shaped tower of small cream puffs fastened together with caramel, or the Norwegian *kransekaka*, a pyramid of as many as twenty-six pastry rings, gradually decreasing in size from bottom to top, and iced and decorated. These may be part of a birthday celebration but are more likely to be the centerpiece for a wedding or, perhaps, a christening. In Korea, steamed rice cakes of various kinds, usually made of layers of ground rice alternating with a bean paste, are served on birthdays but also on other special days.

However, in many parts of the world and especially in the West and countries influenced by Western traditions, by far the most popular food for celebrating a birthday is the birthday cake, complete with decorative icing and glowing candles. In the United States, birthday cakes, especially for children, are essential to the celebration. The custom cuts across all economic, racial, and religious lines. Although elaborately decorated cakes also are used to mark events like weddings, farewell parties, and other major events, the birthday cake is distinctive because of its candles. Any depiction of a circle topped by a one or more candles is recognized at once as a birthday cake.

#### Birthday Celebrations

Birthdays of powerful and wealthy individuals have been celebrated for millennia. The Bible's book of Genesis (ch. 40:20) indicates that Egyptian pharaohs organized festive events around their birthdays and, according to Dalby and Grainger in *The Classical Cookbook* (p. 32), so did Romans in far-flung parts of the Empire. After the Middle Ages, birthdays began to be celebrated by others of wealth and position. Eventually, a growing middle class in the United States in the post-Civil War period began to emulate the customs and manners of their more affluent fellow citizens.

Although there are a number of cultures in which birthdays are not observed, particularly in Africa and the Middle East, usually a birthday is regarded as a rite of passage marking an individual's progress through the life cycle. Certain points along the way may be regarded as more important than others: for example, a first birthday or a sixtieth for a Korean; a fifteenth for a girl in the Latino community or a sixteenth in some other cultures in the United States, a twenty-first, fiftieth, or seventy-fifth for an American, or any birthday year which ends in a zero for a Dane. For such occasions a cake with candles usually is considered essential and extraordinary efforts may be made to provide it. A birthday cake requires a social gathering and ordinarily would not be eaten without others being present.

**Cakes and celebrations.** The birthday cake tradition in the United States is little more than a century old, but the relationship of cakes and celebration has a much longer history. It was traditional in Roman times, especially for those reaching fifty years of age, to be feted with special cakes, according to Toussaint-Samat in *History of Food* (p. 32), but the cakes of Roman times, and for many centuries after, consisted mainly of cereal grain meal moistened with water or wine, and perhaps leavened with some form of yeast. Like small pancakes, they were baked on a griddle and picked up and eaten like cookies.

#### The Development of Modern Cakes

During the Middle Ages in Northern Europe there was little distinction made between bread and cake. Both were leavened with yeast and sweetness was not an important

characteristic. Alan Davidson has written in *The Oxford Companion to Food* (p. 123) that it was not until the late fourteenth century in Europe that professional cooks were able to create immense yeast-leavened cakes filled with dried fruits for special occasions. In the sixteenth century, Italian and French pastry cooks began to develop lighter baked goods using batters based on egg-and-sugar foam instead of yeast. As their methods spread to other parts of Europe, cakes began to change rapidly, although still requiring a professional baker.

**Chemical leavens.** Leavening baked goods with chemical substances, particularly pearlash, a refined form of potash, was in use by professional bakers in Europe by the mid-seventeenth century, according to Witteveen in *Petits Propos Culinaires* #21 (pp. 66–68). But pearlash, saleratus, ammonium carbonate, and other substances known as “yeast powders,” also used by home cooks in the United States by the end of the eighteenth century, imparted an unpleasant taste, particularly to delicately flavored baked goods. In 1863 two pharmacists in Indiana finally succeeded in developing the right blend of baking soda and cream of tartar to produce baking powder. Much earlier in the nineteenth century, the cast iron stove had come into use, and as home bakers learned to employ it in concert with chemical leavens, the modern-day layer cake became possible.

At that time, preparing cake ingredients still involved a lot of tedious work, but later in the century, many labor-saving devices for cooks—egg beaters, standardized baking pans, measuring cups and spoons, and ice boxes—appeared. What once was accessible only to a person wealthy enough to hire and outfit a professional cook had become possible for home cooks everywhere to produce successfully.

**Twentieth-century cakes.** By early in the twentieth century, women’s magazines and their advertisers were spreading the word not only about modern kitchen equipment and products that made baking a cake quick and easy, but were introducing their readers to recipes for layer cakes with glorious frostings and luscious fillings as popular desserts, especially in the American South. Since then, except for the introduction of the chiffon cake in 1948, and cake mixes at about the same time, the contemporary cake has not changed substantially. It is a baked, sweetened creation leavened with eggs or chemical leavens perhaps with the addition of eggs so that it is tender, light, and porous in texture. Usually, but not always, it contains wheat flour or a substitute like finely ground nuts. It may contain a substantial amount of fat or none at all.

### Birthday Cakes

The great cake, a large, lavish creation, was the centerpiece for any Early American party at which it appeared. Making it was difficult, time-consuming, and costly. As Louise Conway Belden points out in *The Festive Tradition*:

First birthdays are a rite of passage for most American children, and part of the fun is to get down into the food. © ARIEL SKELLY/CORBIS.

*tion: Table Decoration and Desserts in America, 1650–1900* (pp. 184–190), its appearance made the event special and festive.

Lavishly decorated cakes continue to be symbolic of life’s festive and dramatic moments, and birthday cakes are expected, above all, to be dramatic in appearance. Only wedding cakes are more elaborate. Besides highlighting an individual’s birthday as an important event, today they often are used as spectacular centerpieces for public occasions in order to provide a photo opportunity or other publicity. Size and appearance are the first consideration; the cake’s flavor and texture may be of less concern.

A contemporary American birthday cake is usually tall, composed of two or more layers or baked in an angel food, bundt, or other tube pan. It often is a unique creation, shaped and decorated to please the birthday celebrant (a clown cake for a child, or a hobby-related cake for an adult). Icing with elaborate decorations of gum paste (which has been made in the Middle East since before the end of the twelfth century) and the generous use of color, borrowed by medieval Europeans from Arab

cuisine, add to the dramatic effect, but are not essential. The cake's primary distinguishing characteristic is that it is topped with candles.

**Candles.** Light from the sun or from fire had very early religious and mystical significance, and rituals using light in the form of candles became part of religious ceremonies surrounding weddings, funerals, and other important human events, according to O'Dea's *Social History of Lighting* (pp. 34, 139–143). Candles also are associated with the measurement of time, and were used in the late ninth century by England's King Alfred to measure the hours of the day. In the Judeo-Christian tradition they have been used to symbolize the passage of time (at Advent or Hanukkah). The candles, rather than the cake itself, connote a long span of time.

Using very small tapers to light a special cake, with the number of tapers equal to a birthday child's age, seems to have begun in Germany in the late eighteenth century or earlier, judging by a letter written in 1799 by the German poet and dramatist Johann Wolfgang von Goethe, in which he referred to the tradition of *Kinderfest* (Goethe, pp. 114–115).

**Birthday cake rituals.** During the twentieth century, birthday celebrations spawned a host of traditions, rituals, and objects related to the festive cake. Although these vary among families and groups, when the cake appears, it is almost always accompanied by the singing of the "Happy Birthday" song, usually in English, even in non-English-speaking countries in Europe and Asia. In Spanish-speaking countries of the Western Hemisphere, it often is sung in both Spanish and English. Spain and Denmark have their own birthday cake songs, with other words and tunes.

The honoree is encouraged to make a secret wish and attempt to blow out all the candles with one breath to ensure that the wish will be realized. Despite various theories that have been advanced, the true origins of this custom are unknown. After the candles are extinguished, the cake is cut and distributed to guests. For young children, whose celebrations are more focused on their ages and growth, there may be attempts by child guests, particularly in Spain and Northern Italy, to pull the birthday child's earlobes, once for each year of age, just as in the United States, spans may be administered, finished off with "and one to grow on."

### Development of an Industry

A global industry has grown up around the birthday cake tradition. Hundreds of kinds of cake decorating supplies are sold, in small shops and from huge warehouses: retail, wholesale, by mail and on the Internet. The techniques, supplies, and equipment are available to residents of even the most isolated rural areas. The industry also has published hundreds of profusely illustrated instruction books describing how to use the tools and supplies to create fanciful cakes. Women in many parts of the

world have learned by using books or taking classes to decorate cakes for family and friends and many have gone on to establish a career in cake decorating.

Bakeries, pastry shops, and supermarkets in the United States do a thriving business in birthday cakes that can be decorated with frosting, gum paste flowers, or little plastic figures and carry a standard piped-on icing message like "Happy Birthday," or they can be customized for special orders in as elaborate a form as any purchaser's imagination and purse will permit, including having color photos reproduced on the iced cake's top surface.

Birthday candles reflect the global nature of birthday cakes. Some candle boxes carry safety directions in as many as five languages, and list manufacturing sites in Asia, Europe, and the United States. They are available in many sizes and lengths, all colors, metallic finishes, stripes, polka dots, and fanciful shapes such as cowboy boots, toy trains, or clowns. There are candles shaped like numbers for use when one taper for each year would be impractical, musical candles, and trick candles that re-light magically after being blown out.

**BISCUITS.** The word "biscuit" is derived from the Latin *panis biscoctus*, "twice-baked bread." From the six-

teenth to the eighteenth century, forms of the word included *besquite* and *bisket*. Similar forms are noted in many European languages. “Biscuit” covers a wide range of flour baked products, though it is generally an unleavened cake or bread, crisp and dry in nature, and in a small, thin, and flat shape. It has a number of cultural meanings. In the United States, a biscuit is a soft, thick scone product or a small roll similar to a muffin. The British biscuit is equivalent to the American cookie and cracker. These latter terms are relatively modern. “Cookie” comes from the eighteenth-century Dutch word *koekje*, a diminutive of *koek* (cake). “Cracker” is a North American term that also came into use in the eighteenth century, connoting the sound of the wafer as it was chewed or broken (at this time, “cracker” was also used to mean a firecracker or a noisy person or object).

Biscuits have evolved from different aspects of baking practices such as tarts, pastries, short cakes, and sugar confectionery. They have given rise to the wafer, macaroon, cracker, sandwich, snap, gingerbread, honey cake, rusk, and water biscuit. Some, like the wafer, were baked in the Middle Ages; others are of more recent origin, such as the “fancy biscuit,” an early-nineteenth-century invention of British bakers that led to the development of a biscuit industry, which was later exported throughout the world. Biscuits are divided into two main groups. The first are plain or have a savory flavoring. The second type are sweet or semi-sweet in character.

Biscuits are made from a number of ingredients. Flour is the most basic and important. Different types give a range of textures and crispness. Wholemeal wheat flour is used in the “digestive,” “sweetmeal,” or “wheatmeal” type of biscuits. Oatmeal forms the basis of oatmeal biscuits. Rice flour and corn flour add flavor. Fats give the biscuits their “shortness.” Butter and lard are the main fats, though these are augmented by vegetable and other refined fats. For fancy biscuits, sugar is an important ingredient, and introduces a range of tastes. It is added in several forms: processed as caster and Demerara sugars, syrups, honey, and malt extract. These have a range of consistencies and may help to bind together other ingredients. Aerating and raising ingredients, such as baking powder (bicarbonate of soda and tartaric acid), make the biscuit light. Flavorings are also added. These include dried fruit, nuts, chocolate (powder or chips), spices, herbs, and flavoring essences such as vanilla. The dry ingredients are bound together with eggs and milk (fresh, condensed, or dried) or water. Biscuits have a high energy content, ranging from 420 to 510 kcal per 100 g.

The mechanized process of biscuit-making is rapid and continuous. The ingredients are mixed into a dough that is then kneaded and rolled to a uniform thickness. Biscuit shapes are cut from it, and placed in a traveling oven. Some biscuits require special preparation and cooking techniques. Biscuit-making has become increasingly and highly mechanized since the early nineteenth century, when technological aids were limited and it was

A circa 1896 chromolithograph showing “Zoological Biscuits,” the original name for animal crackers, which were introduced in England in the late 1870s. ROUGHWOOD COLLECTION.

highly labor-intensive. They can be baked commercially or in the home.

Most biscuits are distinguished by their appearance: round, square, oblong, finger-shaped, or fancifully impressed with designs. Plain biscuits are normally punched with a cutter or docker, to increase crispness during baking. Fancy biscuits can be covered with sugar, icing, or coated (fully or partially) with chocolate. Each type of biscuit also has its own commercial name, which refers to ingredients, a designation (sandwich, wafer, macaroon, or cracker), texture, eating qualities, and the time when it was to be eaten. The range of biscuits has increased over the past 150 years. Huntley & Palmers, of Reading, England, a world leader in biscuit production, sold around 130 varieties in 1870; by 1898, this increased to over four hundred. Some became well established and have a long history. For example, the “Abernethy biscuit,” a proprietary biscuit based on the captain biscuit, was devised by Dr. John Abernethy (1764–1831), chief surgeon at St. Bartholomew’s Hospital, London. Some biscuits have been eaten in large

## THE AMERICAN BISCUIT—A DIVERGENT TRADITION

In Britain and most of Europe, the biscuit follows a direct lineal descent from the Latin *panis biscoctus* (literally twice-baked bread), but in North America broad inconsistencies have emerged in the way this term is used in advertising and in common speech. For light baked goods with a crisp, brittle texture, two terms are in common use: “cracker” and “cookie.” Historically Americans also used the word “biscuit” like their British cousins, as in the case of the ship biscuits or water biscuits of the early 1800s. Both of these foods are called crackers in the United States.

The old water biscuit of the nineteenth century has become the oyster cracker of seafood restaurants and oyster houses. The ship biscuit, with its light sprinkling of salt, has become the boxed cracker of the supermarket. Nabisco Saltines were one of the first of this type marketed commercially on a national scale.

However, Americans call the soft crackers of Maryland’s Chesapeake Bay area “beaten biscuits.” This is a cracker made with high-gluten flour and water that is beaten (the technical term is “broken”) until the dough becomes soft and spongy. When baked, the biscuits are tender and fluffy as though made with yeast. Out of this species of cracker evolved the fluffy raised biscuits made with baking powder that are popular in the South. These soda biscuits, as they were once called, represent a type of bread substitute served with gravies and various fricasseed foods. In the American South they are almost universally eaten at breakfast.

Two common denominators unite all types of American crackers. The first is that they are not sweet, and therefore they are not considered dessert foods. The second is that they are “docked,” the baking term for punching tiny holes into the dough so they become light and brittle once they are baked. Docking prevents the dough from shrinking and becoming tough. The old baker’s tool

used for making the holes was called a biscuit dock, normally a wooden handle attached to a stamp featuring numerous spikes arranged in whatever pattern the baker wanted for his or her crackers. Many docks featured the baker’s initials or a simple pattern, such as a ship’s anchor for a ship’s biscuit.

When sugar is added to these simple recipes, American terminology changes. The crackers become wafers, and if fat of any kind enters into the recipe, the wafers graduate to cookies. The term “cookie” was borrowed from the Dutch, who settled in New York in the early 1600s. The word simply means a little cake, and “little cake” is what most cookies were called in early American cookbooks, just as they were in England. By the 1790s, however, the New York term began to show up in many places outside of that state.

The popularity of the term increased because of its connection with the fashionable New York New Year’s cookies, highly ornamented stamped cookies served during New Year’s Day entertainments. The word moved into American cookbook literature and eventually came to encompass any crisp, sweet finger food. But one further distinction has developed. “Cookie” is applied to foods of this kind that are either homemade or intrinsically American. How is this known? Chinese fortune cookies were invented in the United States in the 1840s under the name of motto cookies. They are not foreign. By this same rule, imported French champagne biscuits are not called cookies. Likewise the Italian *biscotti* served at nearly every coffee bar would never be characterized as cookies. Cookies are comfort food. Cookies are what children are allowed to eat. The word separates what is recognizable and American from all the rest.

*William Woys Weaver*

quantities. The Digestive (or Wholemeal) and Rich Tea became market leaders in Britain from 1949 onward. Other sorts fell out of favor, but new varieties are being continually developed as a result of consumer demand, changing tastes, and innovations in production techniques. Chocolate-coated biscuits started to become popular in the first decade of the twentieth century.

Some biscuits have become cultural markers. The snickerdoodle, flavored with nutmeg, nuts, and raisins, is a speciality of the Pennsylvania Dutch. The gingersnap, a thin ginger biscuit, is popular in Sweden. Povorone is a Spanish and Mexican biscuit of pastry dough flavored

with nuts or cinnamon, rolled in icing sugar after baking. Shortbread, a rich, short biscuit that is a speciality of Scotland, is exported throughout the world. Traditionally, it was a festive food eaten at Hogmanay (the eve of New Year’s Day), though it is now eaten on everyday occasions.

Biscuits are sold in several distinctive ways. They are marketed either as a single variety or as an assortment. Some of these, such as Victoria Assortment, are well-known in England and Canada. Originally, fancy biscuits were sold as novelties. They were kept in highly decorated tins, which are still sold, but have been largely re-

placed by other forms of packaging. The earliest tins held 228 g; later ones extended to 4.5 kg. They were sold in tens of thousands, especially at Christmastime. Biscuit tins have become something of a cultural phenomenon quite separate from the biscuits themselves, since the empty tins are commonly reused as household furniture, for storage, or as decoration.

The role of the biscuit in the diet has also changed. In the early nineteenth century, the fancy biscuit was an expensive novelty, eaten only by the upper classes, and played a relatively minor role in popular diet. Only when the time of meals altered did the role of biscuits increase, being eaten at luncheon and afternoon tea. However, it was not until the 1960s that quality biscuits were within the range of most family incomes, especially in Britain. Biscuits have adapted to a range of uses. They have become health foods (sold in pharmacies), as well as slimming or digestive aids. They are now accompaniments to hot drinks, alcoholic beverages, courses of a meal (usually with cheese), snacks, or substitutes for bread, like the old ship's biscuit, eaten by men on long sea journeys. Biscuits have also assumed a place in popular folklore, for they surface in such expressions as "take the biscuit," which in Britain means the most surprising thing that could have occurred.

**BODY.** The intricate relationship between food and the human body finds expression in virtually all dimen-

sions of human existence: from physiology to psychology, from the domestic sphere to that of political economy, from the societal to the symbolic. In exploring the ways in which food and its consumption are articulated in the forms and images of corporeality, it bears note that the human body, per se, is an abstraction. As gender studies scholars have maintained, there is no such thing as a neutral "human body": every human body is individually unique in a multiplicity of ways (most basically, at the genetic level). In addition, all human bodies are sexed—be they female, male, or born hermaphrodite. For heuristic purposes only, then, it is convenient to generalize about "the human body."

#### Human Growth and Development

The size and shape of an individual human body (what biologists call "phenotype") is the product of the interactions over time of the genetic makeup ("genotype") and environmental influences, including behavior. Morphology, or physical form, derives from hereditary, endocrinological, metabolic, maturational, environmental, and lifestyle factors, yet the relative weight of these effects may vary depending on the somatic trait in question. For example, adult height is under rather high genetic control, whereas adult weight has a relatively low degree of heritability. There is strong evidence, however, that both energy expenditure and the basal metabolic rate enjoy a significant genetic component; likewise, gene regulation is pronounced in the distribution, or patterning, of body fat at all stages of the life span.

Growth, in terms of the progressive development of adult proportions, is measured linearly (by height or length of limb bone); in the expansion of girth, or surface area (by quadratic measures); and in terms of volume, or mass (by cubic measures). Aberrations in any of these dimensions can arise from genetic abnormalities or environmental stress, in the form of malnutrition, disease, toxins, accidents, psychosocial stress, and/or other insults to the developing organism. Human growth is so highly sensitive to environmental forces that it provides a reliable indicator of the quality of the environment, although even under stress the body maintains proportionality, in what has been called the "harmony of growth." Moreover, short-term or seasonal sources of stress need not permanently compromise the developing body, since humans possess the capacity for "catch-up" growth—a rapid increase in growth velocity that restores a child to predicted size—in weight and to a lesser degree in height. Despite its sensitivity, human growth thus appears to be a "target-seeking process" that seeks to move back to its individual trajectory when driven off course (Johnston, p. 318). The ability to recover is a function of the timing, duration, and intensity of insult, plus the quality of the post-insult environment. Data suggest that weight recovery from severe caloric and/or protein shortages can be achieved (in both children and adults), with lean muscle tissue synthesized first, followed by the

laying down of adipose tissue. However, weight gain in itself does not necessarily guarantee a return to normal health, as the body's chemical composition and anatomy may be in danger of disequilibrium without attention to key micronutrients during the recovery process. With respect to stature, chronic stress in childhood can lead to permanent stunting in adult height. It is estimated that approximately one-third of the world's children are stunted in height in comparison with averages compiled for children in North America alone.

Under normal circumstances, human growth and development from conception to maturity follow a patterned trajectory. This trajectory is characterized by a rapid velocity of post-natal growth (with growth rate at its fastest in the first year of life); a steady growth rate with a lower, decelerating velocity during childhood; a juvenile growth spurt around the age of seven or eight (in about two-thirds of healthy children); and the onset of adolescence, with a markedly accelerated growth spurt, beginning for girls at age ten, on average, and for boys at age twelve years (in Western societies, yet later in stressed ecosystems). With the onset of adolescence, the relatively similar childhood body shapes and compositions of the two sexes undergo maturational processes that lead to marked differentiation. Maturation involves skeletal changes, such as the female's wider pelvic girth relative to shoulder width; muscular changes, with males exhibiting a more dramatic increase in accretion of muscle than do females; changes in adipose tissue and fat patterning, with females adding both central body and limb fat, and males losing fat from the subcutaneous layers (superficial under-the-skin fat, as opposed to deep body fat); and changes in secondary sexual characteristics, such as pubic hair and breast development. Growth ceases on completion of puberty after the period of peak growth velocity, whereupon the human body attains adult stature and achieves full reproductive maturity.

The most striking features of the adult stage of life are its stability (homeostasis) and its resistance to pathological influences. With advances in nutrition, medicine, and hygiene and a resulting increased life expectancy at all ages, more humans today live sufficiently past the reproductive years to experience chronic disease and failing physiology. Senescence—defined as cumulative, universal, progressive, irreversible, and degenerative aging—does not appear to be under tight genetic control. Rather, aging is a multi-causal process, and most pathologies relating to age (for example, cancers, heart disease, and late-onset diabetes) are probably culturally and environmentally specific. However, there is a general tendency for both sexes to experience age-related losses in stature and in muscular (lean body) mass, coincident with a decline in total energy requirements. Biological aging in non-Western populations tends to be associated with declining fatness as a percentage of total body composition; in contrast, industrialized populations tend to experience age-related increases in fat.

## Human Morphological Variation

As a result of the dynamic gene-environment interactions taking place from birth to maturity, body size and morphology exhibit a wide range of variation within and between populations. Variation in body shape at a population level may, in part, mark a phenotypic manifestation of the evolutionary forces of natural selection, wherein statistically normal adult morphology is regulated by genetic adaptations to specific ecosystemic and other environmental constraints. For example, there exists a clear geographical pattern that, in colder habitats, mean body weight is greater, which might assist in the maintenance of core body temperature. Likewise, low weight may confer a thermoregulatory advantage in tropical climates, where, too, greater skin surface area (with pores) as a proportion of weight can assist with the dissipation of heat through perspiration.

In addition to genetic differences, there are many environmental and behavioral factors that influence body shape. Nutrition and overall dietary intake play central roles, as do energy-expenditure activities, disease, lifestyle, and socioeconomic status. Variance in basic caloric intake (measured as an excess or deficit in energy balance) is a major determinant of visible differences in body morphology, mainly in the ways that caloric excess shapes subcutaneous fat deposition. Simply put, eating plays an increasingly prominent role in determining what we look like, and the kinds of cross-population and intra-individual variations we see. Fat is one of the most labile tissues of the body and alters according to both genetic and environmental factors. Ethnic differences in subcutaneous fat thickness suggest genetic variation in fat patterning among populations, with peoples of European ancestry exhibiting a more peripheral than central pattern of fat distribution (limb fat over visceral fat) than those of African and Asian ancestry. Across all ethnic groups, there is marked sexual dimorphism with regard to total body fat and fat patterning, with post-adolescent females averaging approximately 20 percent in body fat composition, whereas males average 12 percent. Fat patterning is related to health status in direct and indirect ways; for example, there is strong evidence that body fat at greater than normative values (relative to gender), especially in the form of central body depositions of adipose tissue, correlates with increased risk for cardiovascular diseases and for the metabolic malady of late-onset diabetes (non-insulin-dependent diabetes mellitus).

Processes of societal “modernization,” including increased population mobility, provision of social services, and industrialization (the transition from a predominantly agricultural mode of subsistence to a cash-based economy) have all influenced body shape and size, in both positive and negative ways. Positive effects have come through improved health care and education; negative effects through the growing preponderance of Western lifestyles and consumption of highly processed, energy-dense foods (such as candy and “fast food”). Widespread

increases in levels of obesity (often coupled with malnutrition) have been common in low-income as well as middle- and upper-income communities, and throughout urban, peri-urban, and rural areas. Medical obesity (generally defined as an individual who weighs 25 percent more than the expected weight for a given height and body frame) has become particularly acute among recently modernizing populations of the so-called New World regions, that is, the Amerindians of the Americas, the Aborigines of Australia, and the Polynesians of the Pacific islands. It is unclear whether these populations may be genetically susceptible to late-onset diabetes triggered by rapid social and economic change, or whether undernutrition during fetal and infancy years may be an underlying factor. While in the developed (some might say overdeveloped) countries excess energy (caloric) intake relative to expenditure presents the greatest food-related health problem, in much of the world undernutrition is still a major cause of morbidity and mortality.

### **Culture and Excess Food Consumption**

Ideologies about the body and beliefs concerning ideal body size and shape are highly culture specific and, as such, transform over time, as cultures themselves undergo changes in subsistence, politics, religion, aesthetic tastes, and cross-cultural contact.

Contrary to the medical diagnosis of obesity, social definitions of obesity vary cross-culturally and across different historical eras. In traditional societies, excess body weight has generally been regarded in positive terms. Its value may even be culturally elaborated to such an extent that certain members of the group are deliberately fattened, especially in communities living in environments experiencing extreme seasons or marginal subsistence. For example, in past times when food supplies were irregular among the Nauru peoples of the Pacific, young women were fattened to improve their reproductive performance. Herein, the reproductively viable woman “was supported in her role as the creator of new life, in a community which perceived itself to be under demographic threat” (Ulijaszek et al. 1998, p. 410). Even when Nauru puberty ceremonies involving fattening practices diminished in importance as a result of the introduction of a cash economy, food as a marker of prestige persisted. Likewise, ritual fattening of Annang women in Nigeria is believed to enhance fertility, whereas, among the Azande of Central Africa, fatness is still associated with higher social status as well as greater fertility.

In some cultures, fatness has not only been desirable, it has been evocative of desire, particularly sexual desire. During the Chinese Tang Dynasty (618–907) and for long thereafter, plumpness was the standard of beauty for women; wealthy women were over-fed to levels of excessive obesity. Today, Chinese phrases still equate plumpness with health and good fortune; conversely, phrases associated with thinness indicate poor physical and social position.

Turning to prehistory in this context, it is worth noting the numerous Paleolithic statuettes of obese, voluptuous female figures that have been found over a broad geographical region of present-day Europe. The remarkable uniformity of female figurines, which are almost invariably obese and far outnumber male figurines (none of which are corpulent), suggests that a shared perception of a particular female form existed during Paleolithic times. The most famous of such figurines—the Venus of Willendorf—dates from 26,000 to 22,000 years ago. While we may never know whether the Venus of Willendorf was an actual woman, a fertility-cult idol, or a “mother” goddess, she likely represented a widespread ideal of femaleness, one that emphasized obesity. Based on the life-like depiction of the fat patterns and other features of the statue, it has been suggested that she must have been modeled on a real human subject. If so, she would most likely have been exempt from food-gathering and other high-energy exertion activities, implying that collective food resources were devoted to her care.

The positive value accorded to fatness in some cultures has generally been interpreted as a response to the vagaries of uncertain food supply, wherein individuals with larger body size represented better reproductive potential, higher social status, economic success, and/or better survivability during times of shortage. Body fatness does in fact confer considerable advantages in buffering adversity and promoting female reproductive success: the energy store of body fat in adequately nourished women is usually equivalent to the energy cost of a pregnancy. There is thus a direct, biological equation between body size and individual health, and by extension between the body size of group members and group welfare. Since physical strength derives from food (that is, adequate nutrition and caloric intake), controlling a secure food supply is a source of power, and a marker of such, resulting in a symbolic connection: food not only converts into, but comes to symbolize, fat, flesh, mass. Excess body size might reflect food security, signaling the endurance of the collective and its demographic (hence, politico-military) strength. The obese, voluptuous female may literally embody the practical and ideological values of food. Likewise, the pregnant or lactating female figure is a corporeal sign of the body as life-giving food, itself a source of survival for future generations.

With the rise of industrialization, the majority of the population has become emancipated from direct engagement in the food quest and food production, while at the same time food has become more readily available to all.

The positive value and the aesthetic desirability of obesity common in traditional societies tend eventually to subside with modernization. In late-twentieth-century Western societies, fatness became associated with sloth and laziness, and the cultural ideal emphasized a slender body form and even implied a moral virtue related to thinness. In spite of these new ideals and well-documented negative health effects of being overweight,

obesity has nonetheless emerged as an epidemic health problem worldwide (reaching levels as high as 60 percent of adults in the contemporary United States). Tragically, moreover, the excessive ideals of thinness allowed to perpetuate in the fashion and cosmetics industries have contributed to the rise of another major public health crisis in Western societies, in the form of eating disorders, such as self-starvation, or anorexia nervosa.

### **Ideologies of the Anorexic Body**

Food's central role in mediating the cultural construction of the body is as true in the case of such wasting diseases as anorexia nervosa as it is for obesity. An extremely complex psychological and somatic illness, anorexia nervosa is a life-threatening eating disorder defined as a refusal to eat that results in a body weight of less than 85 percent of the individual's expected weight for height and age. Features of anorexia that shed light on the relationship between the body, the self, and culture include an intense fear of gaining weight, a distorted body image of being fat (even when the anorexic may be emaciated in actuality), absence of regular menstrual periods, and in some cases, binge eating followed by self-induced vomiting or laxative abuse. Anorexia predominantly strikes females, especially in their teenage years; only 10 percent of sufferers are males. Conservative estimates suggest that 1 percent of females in the contemporary United States develop anorexia, and approximately 4 percent of college-age women in the United States suffer from the binge-eating disorder of bulimia.

Anorexia in its contemporary form is generally regarded as a negative symptom of the current popular culture ideal of female slenderness that valorizes an emaciated and androgynous supermodel-type of figure, characterized by an unrealistically thin waist, willowy limbs, and small breasts. The disease is thus shaped by the cultural concept of the female body in the West, a concept in which food and food symbolism play a central role alongside gender roles and expectations. According to feminist theories, patriarchal ideologies juxtapose the masculine body as an active working thing (energized by caloric intake and a very carnal, consuming relationship to the external world at large) against the feminine body as a passive vehicle intended to provide gratification, which exists in order to be used, to be itself consumed. In short, the masculine subject depends for its existence on the construction of the feminine object as an arena for action and penetration.

In this context, anorexia has been interpreted as both a symptom of a woman's imprisonment to patriarchal society and as an attempt to resist its pressures. On the one hand, an anorexic woman enslaves herself to the impossible ideals of thinness, and by practicing self-starvation literally internalizes and embodies dominant culture's tacit attempts to minimize and control her. On the other hand, by not eating, the anorexic attempts to assert autonomy over her body and body boundaries, and thereby

free herself of external incursions. In both events, food acts as a metaphor for all foreign (contaminating) substances, and food abstinence becomes a measure of self-discipline, self-reliance, and purity: the anorexic shuts out the world, with an autonomy on display and visibly performed in the figure of her thin, model-like body. Yet food consumption is also an expression of desire. If women threaten to become active subjects through the expression of desire in the form of a voracious appetite, then the patriarchal definition of womanhood is undermined. In the logic of this equation, "flesh is appetite made concrete" (MacSween) and appetite is a form of voice (Brumberg, p. 19). Female fat thus becomes an external sign of female desire that intrudes into masculine space. While power might commonly be equated with size, it has been noted that, as women become more powerful and visible in society, they also paradoxically become less massive. In other words, the successful woman is a thin woman. On the surface, the dominant theme reads that a successful woman has the willpower to not eat; at the same time, however, there exists a hidden and contradictory subtext: that women should really not be visible or powerful. With a rise in female power, then, there is a corresponding loss of female flesh, and, paradoxically, a symbolic cancellation of female presence.

Hence, by not desiring food, a modern anorexic makes her body desirable according to the norms of dominant society. By making her body a mirror of starvation, she simultaneously makes herself less threatening to patriarchy. These parallels between desire and food, modesty, and morality also underpin a type of "holy anorexia" that pious medieval women were known to practice. In Europe in the early Christian Middle Ages, asceticism—including abstinence from food consumption—was considered a form of religious piety, and anorexia in particular was a chosen path for women wishing to express their religious fervor. Like its modern counterpart, medieval anorexia may have served to order women's behavior according to dominant values, but also to exercise a kind of resistance. In a historical epoch with few or no birth control options, medieval women anorexics (whose symptoms generally included irregular menstruation) could free themselves of the burden of fertility, while manipulating the powerful imagery of female fertility. For both the medieval and the modern anorexic, then, self-starvation has been part of a larger struggle for liberation from a patriarchal family and society, in the former case, to achieve greater spiritual purity and in the latter, to succeed in the secular public sphere.

### **Food and Body Connections**

For a variety of reasons, males are less associated with food and food symbolism than are females, a situation that largely holds across cultures. Ideologies about the ideal male body in contemporary Western societies tend to focus on muscular body build achieved through energy expenditure and exercise regimes, rather than

through food intake or abstinence. Men who suffer from anorexia athletica (compulsive exercise) may abuse food in the form of undereating or binge eating, along with steroids or laxatives, in attempts to achieve a model physique.

Perhaps because of the ideological links between musculature and virility, red meat (primarily beef) has popularly been regarded as “man’s food” in contemporary society. The common cliché “real men don’t eat quiche” captures such gender assignment of food in a Western “you are what you eat” cultural paradigm. Salads are seen, by contrast, as the preserve of women, though not simply based on caloric levels, since while meat has higher calories than lettuce, salad dressings are likely to be calorie-rich. Chinese culture provides another pronounced example of food categorization schemes, wherein most foods possess either a *yin* or *yang* nature, categories that also align with female or male connotations, respectively.

In sum, culture-specific body image plays a prominent role in consumption patterns and types of food consumed, based on gender and dominant ideologies. As food consumption is “worn” by the body through processes of human growth and development, it might be said that beliefs about food are “worn” by the body as a reflection of cultural norms. In various cultural and historical contexts, the body, as an index for food, has come to symbolize individual and collective welfare, fertility, morality, sexuality, power, and/or resistance.

**BODY COMPOSITION.** The term body composition describes the various components that make up a person’s body. The absolute and relative amounts and distribution of these components are relevant to diverse body functions and, thus, influence the state of health and various disease risks. A commonly used body composition model organizes the body to five levels of increasing complexity: from atomic to molecular, cellular, tissue-system, and whole body.

At the atomic level, the body is made up of chemical elements essential for life. Four major elements, oxygen, carbon, hydrogen, and nitrogen, collectively account for more than 96 percent of adult body weight. The remaining are minerals present in the form of salts. Calcium and phosphorus make up the major bulk of remaining minerals, found mostly in bone.

The four elements, oxygen, carbon, hydrogen, and nitrogen, are present at the molecular level in water and as organic compounds. Water serves as a solvent where chemical reactions take place. Protein and phospholipids serve as major structural components of the body. Proteins, glycogen, and lipids that include phospholipids and fats are all organic compounds. Protein, in the form of enzymes and hormones, performs important biochemical and physiological roles in the body. Glycogen reserves are small and used mainly as metabolic fuel. Fat serves as insulation and as an energy store. The two major organic compounds, protein and fat, plus water are usually grouped with the mineral component (osseous and non-osseous) to form the four-compartment model, a model

used most often when considering the nutritional status of a person.

Two alternate groupings of these components used to describe body composition at the molecular level are the division of the body into a fluid and a dry component. The latter is comprised of proteins, minerals, and fat. The second alternative, also referred to as the classic two-compartment model, divides the body into fat and fat-free masses. Fat mass is the most variable as it is affected by energy balance. The fat-free mass is composed of water, proteins, and minerals. This term is used synonymously with lean body mass. This compartment also includes essential lipids. It is metabolically important and its chemical composition is assumed to be constant in a healthy adult.

At the cellular level, the chemical compounds are assembled into either the cellular component (the body's main functional components) or the extracellular supporting components; for example, extracellular fluid and solids, of which the skeleton makes up its major bulk. Because living cells consist of metabolically important structures and an inert fat component, the cellular component is further subdivided into a body cell mass and fat. This three-compartment model of body cell mass, fat, and extracellular components presents a physiological view of the body.

The tissue system level is also of structural and functional importance. Tissues contain cells that are mostly

similar in appearance and function. Tissues and organs are categorized into adipose tissues, skeletal muscles, skeleton, blood, and a "residual" category that includes the skin and visceral organs. Adipose tissue includes fat cells, blood vessels, and structural elements. White adipose tissue is located mainly in the subcutaneous and visceral compartments. Subcutaneous fat provides insulation, and most visceral fat serves as an energy store. Brown fat is present in small quantities in discrete locations and plays an important role in heat production in neonates during cold exposure.

The whole body level of organization involves physical characteristics, such as body size and shape.

Normal Changes Throughout the Life Cycle

**Growth.** The growth process involves an increase in body size and compositional changes of tissues and organs, physiological changes during adolescence, and finally, chemical maturation of tissues and organs to reach a "stable" composition in adulthood (Table 1). Growth in height, weight, tissues and organs, and changes in chemical composition are not uniform. Thus, the relative proportions of various tissues and organs vary at different stages of growth (Table 2).

Length and weight increase rapidly during the second half of gestation and continue to change rapidly through the first year of postnatal life. There is a relative slowing in growth rates as gestation approaches term,

TABLE 1

Anthropometry and body composition of fetus, neonate, and adult							
Parameter	28-week fetus	Neonate		20- to 29-year-old adult		60- to 69-year-old adult	
		Boy	Girl	Male	Female	Male	Female
Body weight (kg)	1.015	3.530	3.399	78	64	83	71
Length/height (cm)	36	50	49	176	163	174	160
Body mass index (BMI)	—	—	—	25.2	24.2	27.4	27.7
Components of whole body (% body weight)

Data on fetuses were calculated from those of Widdowson and Dickerson, and those of Ziegler and coworkers.							
Data on neonates were those of Fomon and coworkers.							
Bone mineral mass for fetuses and neonates were calculated using the equation of Koo and coworkers.							
BMC (g) = 24.2 * body wt (kg) - 11.1.							
Data on body weight and stature in adults were from NCHS for all race/ethnicity groups in the United States.							
Data on body fat and fat-free mass in adults were those of Reference Man.							
Data on water, protein, and bone mineral mass of adult Caucasian males and Caucasian females in the United States were calculated from their relative proportion in fat-free mass using the data of Ellis.							
Data on water, protein, and bone mineral mass in fat-free mass of adult Caucasian males and Caucasian females in the United States were those of Ellis.							

TABLE 2

**Weight distribution of organs and tissues**

	Neonate	Adult	
		Male	Female
Body weight (kg)	3.4 kg	70 kg	58 kg
Organs or tissues (percent body weight)			
Adipose tissue	27%	21%	33%
Skeletal muscle	22%	40%	29%
Skeleton	9–18%	9–18%	9–18%
Visceral*	8%	7%	7%
Skin (excluding hypodermis)	6%	4%	3%

Data were those of Reference Man.

\*Visceral organs include heart, lung, stomach, intestines, liver, gall bladder, pancreas, and spleen.

due to the physical constraints imposed on the fetus. Rapid growth in skeletal muscle and adipose tissue causes a concomitant surge in the relative protein and fat contents in the fetus and a decrease in its relative water content. At the same time, a progressive fluid shift occurs from the extracellular into the intracellular compartment. Progressive mineralization of the skeleton also occurs during this period.

After the first year, growth rate slows until the second major growth spurt at adolescence. Hormonal changes during adolescence cause major physiological differences between sexes. The “adolescent growth spurt” lasts about two to three years and begins earlier in females. In females, there is a larger accretion of body fat. In males, the increase in skeletal muscle mass is more intense and of longer duration. This sex difference in skeletal muscle and fat content persists throughout the adult years. “Chemical maturation” of the fat-free mass is completed during adolescence, when there is a relative decrease in water and a relative increase in fat, protein, and bone mineral mass.

Normally, adult height and weight are reached at about eighteen years of age by females, and twenty years of age by males. The height and weight is 170 cm and 70 kg respectively for the reference adult male, and 160 cm and 58 kg for the reference female. Relative weights of skeletal muscles and adipose tissue are higher, and that of viscera lower, in adults compared with infants. Although relative weight of the skeleton is similar between infants and adults, the adult skeleton has a higher mineral content.

**Aging.** The aging process produces a decline in height, lean weight, muscle mass, and skeletal size. Loss of skeletal muscle and bone mass is related to the age-associated decline in physical activity and to the decline in various hormonal secretions.

**BODY MASS INDEX**

Body Mass Index (BMI) is a useful guide for assessing adiposity. BMI is weight/height<sup>2</sup> (kg/m<sup>2</sup>). It is related positively with body fat content. A high BMI is associated with an increased risk of cardiovascular disease, diabetes, osteoarthritis, and other conditions. However, a high BMI may also reflect a high muscle mass. Thus, other assessments should be performed, and BMI is only one of several risk factors associated with the diseases noted above.

A range of values for BMI has been used to help adults assess their health status. According to the Centers for Disease Control and Prevention (CDC), a healthy BMI for adults is between 18.5 and 24.9 kg/m<sup>2</sup>. An individual with a BMI value of less than 18.5 is considered to be underweight. A BMI value of between 25.0 and 29.9 is considered to be overweight, and obesity is designated by values of 30 or higher.

It is more difficult to interpret BMI values for children and adolescents because of changes in body fat content that vary normally with age and sex in these life stages. As with growth references for weight and height, sex-specific preferences for BMI-for-age are available for ages two to twenty years. Limits have been established to identify undesirable weights in children and adolescents. Those under the fifth percentile on the BMI-for-age references are classified as underweight; those equal or over the eighty-fifth percentile are considered to be at risk of becoming overweight; and those equal or over the ninety-fifth percentile are considered to be overweight.

**Changes in Body Composition under Different Conditions**

**Weight loss.** Prolonged food deprivation causes growth faltering in children and weight loss in adults. Recurrent infections due to poor hygiene and health care may exacerbate food deprivation. Severe weight loss also occurs in diseases, such as malignant cancers, hepatic and renal diseases, and those involving the gastrointestinal tract. Loss in weight in severe undernutrition is due to loss in both body cell mass and fat mass.

Loss in body cell mass and preservation of the extracellular fluid results in an increase in water content in the fat-free mass and an increase in the ratio of extracellular fluid to intracellular volume.

**Weight gain.** Most weight gain involves a mixture of fat and lean tissues with their relative contribution depending on the initial body composition, physiological

## METHODS OF MEASUREMENT

Because of the implications of changes in body composition to health and disease, there is a need for their measurements. Virtually all the major elements—oxygen, carbon, hydrogen, nitrogen, sodium, chlorine, calcium, and phosphorus—can be measured directly by *in vivo* neutron activation analysis techniques. Total body potassium (K) can be measured by whole-body counting of the naturally occurring radioisotope  $^{40}\text{K}$ . These techniques are expensive and are available in only a few centers.

The four-compartment model (fat, water, protein, and mineral) is ideal for assessing growth and nutritional status. Theoretically, fat mass can be assessed from the distribution volume of inert gases; but in practice, it is problematic, and its use remains a challenge. Water can be estimated by measuring the dilution volume of water labeled with stable-isotopes of hydrogen,  $^2\text{H}_2\text{O}$ , or oxygen,  $\text{H}_2^{18}\text{O}$ ; protein may be estimated indirectly from measurements of total body nitrogen by assuming that 16 percent of protein is nitrogen; and the total body mineral contents calculated from total bone minerals which are estimated by whole-body dual-energy X-ray absorptiometry (DXA).

Although fundamentally important, methodological constraints often limit the use of the four-compartment model. Thus, the classic two-compartment model that compartmentalizes the body into fat mass and fat-free mass is used more widely by physicians and exercise physiologists. Fat-free mass, which includes water, proteins, and minerals, can be determined by various indirect methods if one assumes that the relative composition of this compartment is relatively constant in healthy adults. The established “constant” values for the various components of fat-free mass are population- and ethnic group-specific, and applicable only to healthy young white adults. Successful application of the two-compartment model to the young, sickly, elderly, and different ethnic groups requires determination of group specific “constants.”

The earliest method, and one considered to be the “gold standard,” for estimating fat-free mass, is densitometry. The body density is obtained by underwater weighing and assuming a density of  $1.100\text{ g/cm}^3$  for fat-free mass and  $0.900\text{ g/cm}^3$  for fat mass. A more modern air-displacement method has been used to measure body density. Its advantage is its applicability to infants, the sickly, and the elderly. Fat-free mass can also be estimated from measurement of either total body water or potassium, and by assuming that the water content of fat-free mass is 73.2 percent, and that its potassium content

is  $68.1\text{ mmol/kg}$  in adults. Other noninvasive methods for measuring body composition include total body electrical conductivity (TOBEC) and bioelectrical impedance analysis (BIA) techniques. These methods use the principle that the fat-free mass conducts an electrical current better than does the fat mass.

Although information at the cellular level is important, quantifying the compartments may be technically difficult. Attempts have been made to assess the size of cellular compartments in healthy adults by using “constant” values. Body cell mass has been estimated from measurements of potassium multiplied by a factor of 8.33, and extracellular solids from estimates of total body calcium and the assumption that 17.7 percent of extracellular solids is calcium. Dilution volume of bromine or chlorine has been used to estimate the extracellular fluid volume.

Most of our knowledge of the composition of specific tissues and systems comes from studies of cadavers and tissue biopsies. Computed tomography (CT), magnetic resonance imaging (MRI), and ultrasound imaging provide information on subcutaneous and visceral adipose tissues, and DXA provides information specific to the skeleton. Skeletal muscle mass can be estimated indirectly from measurements of total amount of creatinine in the urine over a 24-hour period. Radiology is useful to assess the proportions of bone, fat, and muscles in limbs.

Commonly used techniques at the whole body level are anthropometric measurements of body weight, height, body circumferences, and skinfold thicknesses. These techniques are simple and easy to perform and are well suited for field work or for large-scale studies. Sex-appropriate clinical growth charts available from the National Center for Health Statistics (NCHS) are used routinely for clinical assessments of growth by pediatricians. Two sets of sex-appropriate weight-for-age, length-for-age, and weight-for-length percentile references are available: one for infants from birth to thirty-six months, and another for older children from two to twenty years of age. Two often-used methods that reflect fatness are measurements of skinfold thickness and estimates of the body mass index (BMI). Regional subcutaneous fat distribution can be estimated from skinfold thickness measured with specifically designed calipers. The approximate ratio of upper-body adiposity to lower-body adiposity may be estimated by measuring waist and hip circumferences. Body mass index, calculated from  $\text{weight/height}^2$  ( $\text{kg/m}^2$ ), is often used to assess adiposity.

status, and physical activity. For example, an obese person gains a larger proportion of fat than lean tissues than does a lean person.

Overweight and obesity, and their associated health risks, are of increasing prevalence in affluent societies. In the United States, the incidence of obesity has increased from 12 percent in 1991 to 17.9 percent in 1998.

The significant consequences of increase in adiposity are not limited to net changes in body composition. Specific regional fat distributions appear to be associated with diverse levels and types of morbidity. Higher levels of upper-body obesity, especially of the visceral, is associated with abnormalities of fatty acid metabolism and is related to the higher risks of hypertension, premature coronary death, and type 2 diabetes mellitus.

**Physical training.** In general, physical training increases muscle and bone mass, and decreases fat mass. Gains in muscle mass and losses in fat mass vary with the intensity and duration of usual physical activity. Changes in body composition associated with physical activity are mediated by increases in the secretion of anabolic hormones. These increase lean body mass. Increases in catecholamines facilitate fat loss.

**Immobilization.** Reduction or loss of mobility increases the nutritional risk of obesity or sarcopenia, an abnormally low lean body mass. Prolonged immobilization causes loss of body nitrogen and calcium, hence a decrease in muscle mass accompanied by decreases in muscle strength and decreases in bone density.

**Osteoporosis.** The high prevalence of osteoporosis in the elderly, especially in females, is a major public health concern. Loss of bone mass and deterioration of bone tissue is a feature of the normal aging process that is attributable to an intrinsic deterioration of the ossification process. It leads to increased bone fragility and, consequently, increased risk of bone fracture. Although reduction in bone density affects every individual, in some, loss in bone mass is severe. The skeleton is not uniformly involved; the spine and other trabecular bone are more affected commonly and severely than is the cortical bone of the axial skeleton. The greater severity of osteoporosis in females is attributed to a lower peak bone mass achieved at puberty and estrogen withdrawal at menopause. Other factors causing loss of bone mass are a lack of physical activity and decreased calcium intake.

**BOILING.** The admission of the novice cook that he or she "cannot even boil water" has perpetuated the idea that boiling water is one of the simplest tasks in the kitchen. In reality, it is also a frequently misunderstood and mislabeled culinary technique. Boiling is one of the moist (as opposed to dry) heat processes of cooking, which include pressure cooking, scalding, simmering, poaching, stewing, fricasseeing, braising, casserole-making, double-boiling, and steaming, as well as partial moist-heat processes, like blanching. Through the years, however, these traditional terms for different kinds of moist heat cooking have been variously interpreted and,

Photo showing the physics of boiling water and its change to steam. COURTESY OF PHOTO RESEARCHERS, INC.

of necessity, combined with other culinary methods. For example, a braise, fricassée, and brown stew have their origin in dry heat sautéing but are finished by long moist-heat cooking in stock. Even foods that are specifically labeled “boiled,” such as boiled eggs, boiled potatoes, and boiled coffee, are not entirely cooked in boiling water but rather simmered after being brought to a boil. The pores of food are sealed by being dropped into rapidly boiling liquid, but then the temperature is usually reduced to a simmer (185–200°F)—the suitable temperature for cooking soups, stews, and braises.

Boiling, or *bouiller*, is cooking in boiling water. Water boils at 212°F (sea level), and simmers at 190°F. To fully understand the heating process, Julia Child advises the cook to observe water in its various cooking stages, from tepid to real boil, by testing it and using an immovable thermometer and noting the following temperature changes:

Tepid: 85 to 105°F. The water is comparable to the temperature of the human body.

Warm: 115 to 120°F. The water is touchable but not hot.

Hot: 130 to 135°F. The water is too hot to touch without injury.

Poach: 160 to 180°F. The water is beginning to move, to shiver.

Simmer: 185 to 200°F. There is movement, and little bubbles appear in the water.

Slow boil: 205°F. There is more movement and noticeably larger bubbles.

Real boil: 212°F. The water is rolling, vigorously bubbling, and steaming.

Boiling is affected by altitude. At sea level, water boils at 212°F; at 3,000 feet, it boils at 205°F; 5,000 feet, at 203°F; and 7,500 feet, at 198°F. Because certain foods, like soup, pasta, and vegetables, will cook at a lower temperature, they will take longer to cook.

The boiling process serves two purposes: it destroys organic impurities, and it transforms raw ingredients into cooked foods. Boiling water hardens the albumen in eggs; toughens fibrin and dissolves tissues in meat; and bursts starch grains and softens cellulose in cereals and vegetables. One of the great advantages of water as a cooking medium is that it needs only a vessel and heat to reach and maintain its boiling point, no matter how long or how hard it is heated.

The food scientist Harold McGee maintains that during the boiling process, it is the convection currents in hot water that heat food. The “moist” cooking methods, however, cannot brown foods; consequently, meat and vegetables are normally sautéed in a frying pan before they are simmered in broth or water. Despite this limitation of the technique, by which boiling in water is conducted at a substantially lower temperature level than that of broiling, baking, and frying, boiling is a very efficient process. As McGee notes in *On Food and Cooking*, “The entire surface of the food is in contact with the cooking medium, which is dense and turbulent enough that the water molecules continuously and rapidly impart their energy to the food” (p. 615).

The old adage “a stew boiled is a stew spoiled” can be applied to almost every other kind of food because lengthy cooking at high temperatures toughens the proteins in meats, fish, and eggs, and the rapid bubbling breaks up delicate foods. While recipes either call for foods to be immersed in cold water and brought to the boiling point or plunged into boiling water, they almost never indicate boiling for a protracted period of time. Even so-called “boiled” eggs should be simmered after the initial contact with boiling water. Simmering, then, is often used in tandem with boiling because simmering liquid gently cooks fragile foods and tenderizes tough ones.

Only certain foods, such as vegetables, pasta, cereals, and other grains, are truly boiled in water. In these cases, it is necessary to maintain the boil to ensure their proper cooking. Because adding foods to boiling water lowers the boiling point, it is usually stipulated that the

quantity of water must be at least three times the volume needed to cover the ingredient to offset the lower temperature caused by their addition. In cooking vegetables, particularly, the amount of salted water will insure rapid boiling, thereby shortening the time of cooking and preserving color.

According to Fannie Merritt Farmer, milk should never be allowed to boil because at boiling temperature the casein is slightly hardened, and the fat is rendered more difficult to digest. She advises the use of a double boiler to “scald (196 degrees)” milk heated over boiling water.

### History of Boiling

McGee theorizes that, as a culinary technique, boiling probably followed roasting and preceded baking. Because boiling requires containers that are both water- and fire-proof, the development of pottery at least ten thousand years ago had to precede boiling. And the large pots hanging in the fireplaces of the earliest kitchens attest to the fact that many meals were slowly simmered, sometimes over a period of days. In Taillevent’s *Viandier* (c. 1364) the cook’s activities centered on a fireplace that featured an adjustable pothook from which large cooking pots hung filled with meats, poultry, game, and vegetables. To control temperatures, the pot’s position could be stationary over temperate ashes or could be swung over the hottest coals. Hot coals or logs could also be moved beneath it. This method of hearth cooking continued into the eighteenth century and even later in rural areas. Chef and author John Thorne eulogizes the pot as the emblem of the kitchen and quotes the noted French chef Alain Senderens, who suggests in his *Figues sans barbarie* (1991) that unlike “spit cooking” or the kind of roasting associated with the early “gatherers,” “the cooking of the pot symbolized the feminine domain of the kitchen, family, economy, and, by extension, the civilizing process itself.” By preparing food in boiling water in a pot, the cook took what nature provided and transformed it into thoroughly cooked food. “From this instant,” Senderens believes, “cooking came to indicate the cultural, intellectual, and technological level of a society” (Thorne, p. 239).

Whether gender driven, as Senderens implies, or a matter of historical temperament, the cooking process became more complex and varied because of the invention of pottery at least ten thousand years ago. Furthermore, the word “pot,” contrary to popular belief, does not seem to reflect the Latin *potare* (to drink) or be related to the Spanish *olla* or Italian *pentolone* or *marmitta*—the words for large cooking vessels. Etymologically, “pot” can be traced to Celtic origins: Irish *pota*; Gaelic *poit*; and Welsh *pot*, and there is reason to believe that the word “pot” may have developed initially in northern lands.

Traditionally, boiled dinners and one-pot cooking seemed to be a congenial way of dining in cold climates. From broth-based fondues in Switzerland to the soup kettle that used to hang over the open hearth in the old

farmhouses of Japan’s snow country, variations on sustaining one-pot meals can be found in almost every ethnic cuisine, including the Italian *bollito misto*, Spanish *cocido*, and the French *potée lorraine*. The cold regions of China had a communal dish known in the West as the Mongolian hot pot, named for its distinctive cooking utensil, and a popular contemporary Japanese modification is called *shabu-shabu*.

Asian cooking also has a communal one-pot meal, called *nabemono*, literally “things in a pot,” which is served at home and in restaurants. Diners do their own cooking, choosing whatever meat, poultry, fish, and vegetables they like from platters overflowing with raw ingredients that they cook over a communal pot of sizzling broth. The broth is continually enriched in flavor as the ingredients are dipped into it. Although the *donabe*, an earthenware casserole with thick pottery walls and distinctive shape, requires a portable and substantial heat source to maintain the temperature of the dipping broth, everything from gas rings to an alcohol or canned-heat burner can be used effectively during the traditional lengthy meal.

Pot-au-feu, or “pot on the fire,” consisting of meat, poultry, and vegetables in their cooking liquid, has also been a fixture of French gastronomy since the Middle Ages, and it was dramatized by King Henri IV, who promised his subjects a chicken in their pot every Sunday. In some French cookbooks a distinction is sometimes made between a pot-au-feu, a boiled beef and vegetable dinner; and a *poule-au-pot*, in which a whole stewing hen was used; and a *potée* or mixed pot of ingredients, including pork and veal shoulder and various sausages. Used in every French household, the tall earthenware cylindrical pots known as marmites were the ideal cooking utensils for this meal of meat, poultry, and vegetables, which was brought to a boil in water and then simmered for hours over the fire. A good consommé was thereby produced and a full-course dinner served—clear broth first, the boiled meat and vegetables presented separately. A dish called petite marmite was almost identical with pot-au-feu except that its primary purpose was to be served and eaten all together.

By the time Pierre François de la Varenne’s cookbook was published in 1651, the fine broth that hours of simmering had produced in these one-pot meals had an intrinsic value, and separate recipes for bouillon began to appear for the purpose of enhancing soups and entrees. As did medieval cooks before him, La Varenne kept in reserve one meat stock and one fish stock to make a roux, flavor a soup or stew, and combine with other ingredients for a sauce.

On the other side of the Atlantic, boiled dinners have always been popular in New England, Pennsylvania, and other parts of the country. Prepared like a pot-au-feu, the New England boiled dinner is made traditionally with either corned or fresh beef, and boiled beets on the side, while other sections of the country feature an Irish boiled

dinner that includes cabbage, onions, and new potatoes simmered with the corned beef. Boiled crab dinner, the signature seafood dish of the Chesapeake Bay region, consists of blue crabs placed into seasoned boiling water, cooked, cracked open, and accompanied by melted butter. And Wisconsin boasts a famous Door County white-fish boil.

Among the nutrition conscious, there is growing concern about whether cooking, especially the lengthened cooking of boiling, robs foods of their vitamins and enzymes. The cult of raw food, for instance, has rapidly gained momentum. For such adherents, 116°F is the point beyond which components of the original human diet become “dead,” unhealthy victuals. But nutritionists generally come down on the side of cooked food, both to rid ingredients like mushrooms and meats of toxins and to enhance the pleasures of the table. Boiling and its related moist heat cooking techniques, therefore, are worthy of mastering and a challenge to the cook.

**BOTANICALS.** Botanicals are fresh or dried plants, plant parts, or plants' isolated or collective chemical components, extracted in water, ethanol, or other organic solvents, plus essential oils, oleoresins, and other extractives used for flavoring, fragrance, functional health benefits, medicine, or other biological and technical activities. Many botanicals, broadly speaking, also can be classified as herbs, plants used for flavor, fragrance, or medicinal qualities, such as caraway, parsley, rosemary, sage, and

thyme. Other botanicals fall under the classification of spices, piquant aromatic plant materials, usually of tropical origin, used to season food. Examples include cloves, cinnamon, nutmeg, and pepper. Botanicals commonly are used in foods, drugs, and cosmetics. The cosmetic industry uses over 360 botanical ingredients, classified as “biological additives,” to enhance the fragrance, performance, or consumer appeal of products. Botanicals, either in crude form (whole dried plants or plant parts) or in their isolated or modified chemical constituents, also are used in prescription and nonprescription (over-the-counter) drugs. In addition, over 1,600 botanicals and their derivatives are sold in the United States in a special food category called “dietary supplements.” In commercial trade, botanicals, though not defined as such, generally refer to dried materials of plant origin sold in bulk form as whole, cut-and-sifted, or powdered ingredients.

#### Botanicals in Human Experience

Botanists conservatively estimate that 250,000 species of flowering plants exist on Earth. At least 85,000 plant species worldwide have been documented as being used as medicinal botanicals, at least in folk medicine. The World Health Organization estimates that as much as three-quarters of the world's population relies on traditional forms of medicine, chiefly herbal or botanical medicine. Botanicals used in foods, drugs, and cosmetics are an integral part of daily life.

The human experience in the use of botanicals is inextricably interwoven with human history. The first known historical evidence for the use of plants comes from the Middle Paleolithic burial site in Iraq known as Shanidar IV, a Neanderthal grave containing remains of yarrow flowers (*Achillea* spp.), marshmallow (*Althaea* spp.), and ephedra (*Ephedra* spp.), all of which are botanicals still in use in the twenty-first century.

The Ebers papyrus, dating to 1500 B.C.E., was discovered in 1876. This ancient Egyptian manuscript mentions 876 medicines, most of which are of botanical origins. Undoubtedly, ancient Greek scholars learned from their Egyptian predecessors about the use of botanicals in medicine. The writings of Hippocrates (466–377 B.C.E.) refer to many botanical substances. The starting point for Western medicine, and in particular botanical ingredients used in the West in the nineteenth and twentieth centuries, is the first-century work *De Materia Medica* of Dioscorides of Anazarba in Cilicia. For more than fifteen centuries, all Western cultures depended on this source for information on botanicals. It includes over six hundred botanicals, most of which are in use in the twenty-first century.

#### Botanicals as Food Additives

Over 250 botanical substances are added during food product manufacturing for flavor, fragrance, or technical characteristics, such as coloring, thickening, or preservative activity. These botanicals are used commonly and

extensively, often in the form of concentrated extracts at parts per million levels, as natural ingredient additives for many categories of food products, including baked goods, canned goods, meat products, dairy products, nonalcoholic beverages, and alcoholic beverages. Many botanical ingredients have a long history of use and generally are recognized as safe. However, for a new ingredient, not previously marketed materially in the United States, to enter the American market, it must receive prior approval by the Food and Drug Administration (FDA). The manufacturer (or industry trade organization) may submit toxicological data to the FDA in support of the ingredient's safety.

### Botanicals as Dietary Supplements

In 1994 the U.S. Congress passed the Dietary Supplement Health and Education Act, which created a special food regulatory category for dietary supplements, including vitamins, minerals, herbs or other botanicals, amino acids, or other dietary substances used to supplement the diet by increasing the total dietary intake. Concentrates, metabolites, constituents, extracts, or their combinations also are included in the definition. Dietary supplements are regulated as foods rather than as drugs despite the fact that most such products are intended to provide a health benefit. The vast majority of botanicals available on the American market, from over 1,600 plant species, are sold as dietary supplements.

Many well-known botanicals sold as dietary supplements in the United States also are available in other Western countries, notably Germany, where they are regulated as drugs under a special category called phytomedicines. By definition, phytomedicines include the totality of chemical constituents within a botanical or plant part rather than a single isolated chemical component. Well-known botanicals in this category are garlic (*Allium sativum*), ginkgo leaf extracts (*Ginkgo biloba*), echinacea (*Echinacea purpurea*, *E. angustifolia*, and *E. pallida*), ginseng (*Panax ginseng*), kava kava (*Piper methysticum*), saw palmetto (*Serenoa repens*), St. John's wort (*Hypericum perforatum*), and valerian (*Valeriana officinalis*). In the European markets for these botanicals, quality is strictly regulated. In the United States, it is not; therefore dietary supplements are perceived as "unregulated."

### Botanicals in Modern Medicine

Prescription and nonprescription drugs of botanical origin are used widely in modern medicine, primarily as purified derivatives or partially modified secondary chemical compounds. Remarkably it is estimated that approximately 25 percent of drugs in the average American pharmacy are botanical derivatives. Of 121 prescription drugs in use in the early twenty-first century that originate from 90 plant species, 74 percent were discovered in scientific follow-up of historical or folkloric claims of medicinal value. Botanical derivatives used in chemotherapy include paclitaxel (taxol), extracted from yew species (*Taxus* spp.),

Botanical illustrations provide a rich source for information about historical food plants. This picture of the purple hyacinth bean (*Dolichos labab*) appeared in *Edward's Botanical Register* in 1824 and represents one of the most beautiful scientific renderings of this bean. It was grown as an ornamental in the United States, but the white flowering variety provides an important source of food in India. The bean was also known to the ancient Greeks and Egyptians. ROUGHWOOD COLLECTION.

used for certain forms of breast and ovarian cancer; vincristine and vinblastine, purified alkaloids extracted from the Madagascar periwinkle (*Catharanthus roseus*), used in the treatment of leukemias and Hodgkin's disease; and semisynthetic compounds from mayapple (*Podophyllum* spp.), used in the treatment of testicular and small-cell lung cancers. Nonprescription botanical ingredients include the laxatives psyllium seed (*Plantago* spp.) and senna leaves (*Senna* spp.). Some botanicals are the source of both drugs and foods. Morphine, codeine, and other chemical analogs from the opium poppy (*Papaver somniferum* L.) are used for the management of pain. The opium poppy

is also the source of poppy seeds, used as a decorative and flavoring component in the culinary arts.

### **Foxglove: From Folk Medicine to Modern Botanical**

The cardiac glycosides digoxin and digitoxin, extracted from several species of foxglove (*Digitalis* spp.), are used in the treatment of heart diseases, such as atrial fibrillation and congestive heart failure. This botanical was not well known to the ancients as a medicinal plant. Instead, it was considered a poisonous plant. A British physician, William Withering, introduced the drug to medicine in 1785 in *An Account of the Foxglove and Some of Its Medical Uses: With Practical Remarks on Dropsy and Other Diseases*, published in Birmingham, England, where Withering served as a physician at the general hospital. In 1775 Withering became aware of the secret family recipe of an elderly patient, Mrs. Hutton, in Shropshire, England. She had developed a reputation for curing “dropsy” (congestive heart failure) when physicians had failed. Withering discovered that the active ingredient was foxglove. Crude extracts of the botanical were prescribed widely in the 1800s, although exact dosing requirements sometimes resulted in fatal overdoses. The crude drug and its preparations have a narrow therapeutic ratio. A small increase in dose, only slightly above that necessary for therapeutic results, can produce toxicity. The discovery and isolation in the leaves of the glycosides responsible for the botanical’s pharmacological cardiac effects led to more exact controlled dosage forms with lower risks of toxic effects.

### **“The Dose Makes the Poison”**

Foxglove and its isolated chemicals are a good example of a fundamental principle in the response of a cell, organ, or organism to a botanical drug or food ingredient. The response or expected activity is proportional to the dose. Therefore, research on the effects of a substance on an organism requires measurement of a dose-response relationship. Such information is gathered by measuring responses to appropriately variable amounts of the active agent (usually in laboratory animals). Doses are increased incrementally until 80 percent of the maximal response is achieved. Above the level of 80 percent, usually only small changes in activity are observed. Higher doses also may result in toxic effects. Quantitative analyses of the dose-response curve measure the relative potencies of a drug or extract and help determine at what levels a beneficial or a toxic reaction may occur.

Inhibition or potentiation of a response often involves attachment of a molecule to a cellular receptor site. Targeting cell receptor sites helps direct research to specific activities, such as anti-inflammatory or analgesic (pain-relieving) effects, or to diseases, such as diabetes mellitus or cancer. Mechanisms of action of potential interest often relate to cell receptor site competition. Sometimes effects are mechanical. For example, psyllium seed works as a bulk laxative by absorbing moisture in the in-

testines, thus increasing bulk and stimulating mechanical peristalsis.

A common adage in toxicology is “the dose makes the poison.” In pharmacology, the measure of a substance’s margin of safety is known as the “therapeutic index.” This index is expressed as the ratio of the dose causing harmful effects to the dose causing a therapeutic effect in a specific proportion of individuals. The amount of a substance that causes death in 50 percent of laboratory animals is expressed as LD50 (dose lethal to 50 percent).

### **Botanicals Withdrawn Due to Safety Concerns**

Most botanicals have a long history of apparent safe use. Ingredients may be withdrawn when new information raises safety concerns. Sassafras (*Sassafras albidum*) is an example. Sassafras derives its flavor and fragrances from an essential oil comprised of up to 80 percent safrole. In the late 1950s safrole, then used as a primary root beer flavoring, was banned as a food additive due to concerns over serious liver toxicity and carcinogenicity. The ban was subsequently extended to dried sassafras bark sold for the intended purpose of making an herbal tea. Dried sassafras leaves (used as a base for gumbo filé) must also be free of safrole. Another example of a botanical no longer considered safe is comfrey (*Symphytum* spp.). Popular in the 1970s and 1980s, comfrey leaves and roots were regarded as a virtual cure-all, earning it the name “all-heal.” Apparently used safely for centuries, comfrey was found to contain significant amounts of a class of pyrrolizidine alkaloids that cause a condition known as veno-occlusive disease of the liver (resulting in the occluding or clogging of the major veins in the liver). The rare disease can only be diagnosed with a liver biopsy; thus it went unrecognized for decades. Internal use of comfrey products is restricted or prohibited in many countries.

**BOTULISM.** Botulism is a paralytic illness caused by a nerve toxin produced by the soil bacterium *Clostridium botulinum* and spread by contaminated food or by infection of a wound. The term comes from the Latin *botulus* (sausage), but the vehicle in food-borne cases today is usually vegetables or other food improperly canned at home. Commercial canning is almost never implicated, although a notable case in 1971 left one person dead and several others seriously injured. The illness is rare, with only twenty-five to thirty food-borne cases reported annually in the United States.

*C. botulinum* is a spore-forming bacteria that can lie dormant in the soil for months or years. In a warm, moist, low-oxygen environment, however, the spores can produce vegetative cells that multiply rapidly and secrete a deadly toxin, which attacks the nervous system of the person ingesting contaminated food.

Symptoms of botulism include double vision, blurred vision, drooping eyelids, slurred speech, difficulty in swallowing, dry mouth, and muscle weakness. An antitoxin can be used with early diagnosis, but otherwise treatment involves supportive care, sometimes including a ventilator. A severe case can require months of medical and nursing care and may leave the patient with permanent impairments. Botulism is fatal in about 8 percent of cases, usually from respiratory failure.

Thorough washing can remove the spores and proper heating will destroy them. If, however, the food being canned is not washed properly and fails to reach the necessary temperature for the required time, the spores can germinate and produce toxin in the canned goods.

A pH in the acid range will also kill the spores, so acidic foods such as fruit and tomatoes are less likely to be vehicles than low-acid food such as corn, green beans,

or asparagus. Canners are often advised to raise the acidity of food by adding an acid source such as lemon juice or citric acid.

To avoid the danger of botulism, home canners of low-acid foods are advised to use a pressure canner instead of the unpressurized, boiling-water-bath systems used previously. A temperature of up to 250°F is needed, which can be reached with pressure canners operated at ten to fifteen pounds per square inch. The time required ranges from twenty to one hundred minutes, depending on the food and the size of the jars. Detailed instructions are available with home canning systems, either from the U.S. Department of Agriculture or from an extension agent.

Industrial quality control makes it highly unlikely that commercially canned food will be contaminated with *botulinum* toxin. However, consumers should reject any commercial canned goods that appear swollen or bulging and any canned food with a bad smell or flavor.

In recent years, scientists have recognized an infant form of botulism in which infants ingest spores that germinate and produce toxins in the intestines. This appears to be linked mainly to the ingestion of raw honey, so authorities urge parents never to feed raw honey to babies. There is little danger of this variant of the disease after the age of one year.

**BRAZIL.** The only Portuguese-speaking country in South America and the largest Portuguese-speaking country in the world, Brazil has been called "a country without a memory" by one of the leading guidebooks. Lack of memory, though, should not be interpreted as lack of history, as the mix of cultures in the country's gene pool is rich indeed, with a complexity and variety that show nowhere more than in the food.

Portuguese seaman Pedro Alvares Cabral was thousands of miles from his stated destination of the Cape of Good Hope when he arrived on 22 April 1500 and became the first European to walk on the land that would be named Brazil in 1511. The treaty of Tordesillas, signed in 1494, had divided up the globe and given all lands known and unknown east of an imaginary north-south line 370 leagues west of the Cape Verde Islands to

the Portuguese. By 1532, when the first substantial Portuguese settlement was founded, the die had been cast based on Portuguese experiences in Asia and in Africa. Brazilian sociologist Gilberto Freyre notes in *The Masters and the Slaves: A Study in the Development of Brazilian Civilization* that Brazil was “a society agrarian in structure, slave holding in its technique of economic exploitation, and hybrid in composition, with an admixture of Indian and later of the Negro.” Almost five hundred years later, these three major groups—Indian, Portuguese, and African—continue to form the matrix threads of Brazil’s culinary culture.

### Native Influences

French chronicler Jean de Lery’s 1770 *Histoire d’un voyage fait en terre du Bresil* offers insights into the daily life of the native peoples and reminds readers that the women were responsible for much of the agriculture, the management of the entire house, and all of the cooking. Many of these culinary creations are still a vital part of the country’s menu. Manioc or cassava (*Manihot esculenta*, *Manihot aipi*, or *Manihot dulcis*) remains a major staple. The bitter cassava tuber, which required time-consuming preparation to remove the prussic acid (also known as hydrocyanic acid), was processed into a meal, which formed the basis of the diet. The liquid was also used and became the basis for *tucupi*, a condiment of cassava water, garlic, chili, chicory, and seasonings that is still prized today in the Amazon region. The Portuguese colonists at first confused the manioc with the true yam that they were familiar with from Africa. Soon, though, they were eating such Indian dishes as a form of cassava cake known as *mbeieu* or *beiju*, a cassava porridge or paste known as *mingau*, and *pacoca* or *pacoca*, a pulverized fish and cas-

sava meal that has given its name to a popular contemporary pulverized peanut and sugar candy. Maize (*Zea mays*) was known, but never assumed the importance in Brazil that it had in other parts of Central and South America. Fish was also abundant and played a major role in the diet, with the pirarucu (*Arapaima gigas*) having the place of primacy. Fish was frequently prepared by roasting it in its own fat over a slow fire, then sealing it in earthenware jars. Other varieties of Amazon fish were prepared in this manner as was manatee, which was called *peixe boi* or ox fish.

Green vegetables were scarce, but nuts were consumed, particularly the cashew, as were the sweet potato, peanut, and cacao. Papaya (*Carica papaya*) and guava were eaten, as were pineapples. When the Portuguese brought bananas and citrus fruits, they were immediately adopted by the natives. Ripe fruit was eaten raw and green fruits grilled or roasted. Seasoning was done with chili; in fact the Indians were known for their overuse of the fiery capscicum as well as their abundant use of ginger and of lemon. Freyre cites a Jesuit account that cautions that excessive usage of the three resulted in frequent attacks of dysentery. Another of the lasting contributions of the native Brazilians to the cooking of today’s Brazil has been the cooking utensils. The mortar, earthenware water jug, and wicker sieve, along with calabash utensils large and small, all hark back to the first Brazilians.

### Portuguese Colonization

Portugal at the time of the colonization of Brazil was a nation recovering from a lengthy period of Moorish occupation. Old Portuguese cookbooks like *Arte de Cozinha*, published in 1692 by “a royal cook,” list numerous recipes for “Moorish lamb,” “Moorish fish,” and the like. The everyday diets of the Portuguese in the years after the Moors fluctuated between feast and famine. The upper classes hovered between the excesses required on religious feast days, when meals had to be provided to royal retainers, rent collectors, and religious persons for show and status, and the far more frequent days when bread and radishes were the norm. For the poor, bread and onions were typical fare, and meals of sardines or other fish were a treat; meat was rarely tasted. Much of the agricultural wealth of the country was maintained in the convents and monasteries.

In the new land, the colonists began to shape their diet with the foods they knew either in their Iberian home or in the Asian and African colonies. They brought figs, citrus fruits, coconuts, rice, watermelon, the pumpkin called Guinea pumpkin (West Indian cooking pumpkin or *Cucurbita maxima Duchtre*), mustard, cabbage, lettuce, coriander, cucumbers, watercress, eggplant, carrots, and more. Gabriel Soares de Sousa, in his *Tratado descritivo do Brasil em 1587*, offers a seemingly exhaustive listing of the plants brought. He adds that a green belt of one to two leagues encircled Salvador and provided much of the fruits and vegetables for the capital. Olive oil, butter,

chickens, and eggs all arrived, as did pigs and the art of preserving pork and other meats.

Although the colonists brought an abundance of ingredients with them, they were so preoccupied with acquiring fortunes in the new land that their diets did not markedly improve. All was sacrificed to King Sugar. Cattle were banished because they destroyed the cane, and domestic agriculture was neglected. By the seventeenth century, travelers were astonished to note that large cities had no slaughterhouses as there were no cattle to send to them. The colonists, though, did have a major influence on the cooking pots of contemporary Brazil, not only by transporting and acclimatizing countless plant species, but also by establishing a countrywide culture—that of Portugal, with its abundant use of cabbage and kale, its hearty soups and rich stews, its traditions of grilling, and the Iberian fondness for sweets. (The Iberian “sweet tooth” combines the North African love for sugar and a tradition of intricate confections developed in Roman Catholic convents.) It is to the mother country that Brazil owes dishes such as the dense, rice-filled chicken soup known as *canja*, the strips of leafy kale greens that accompany the *feijoada* that is the national dish, and a national taste for meat and potatoes.

### African Influence

The African hand in the Brazilian cooking pot completes the triptych, most noticeably in the northeastern states, where the plantation system held greatest sway. There, from virtually the inception of colonization, Africans were in control of the kitchens of the Big Houses. In Bahia, they were from the Bight of Benin and the Sudanese regions of West Africa. In Rio and Pernambuco, they were mainly Bantu. All brought their own tastes in food. The religious traditions of the African continent crossed the Atlantic as well, and in the hands of the Big House cooks, many ritual dishes were secularized and joined the culinary repertoire. The *akara*, a bean fritter fried in palm oil by the Yoruba people of southwestern Nigeria, was transformed into the Brazilian black-eyed pea fritter, or *acaraje*; *fon akassa* changed only its spelling to become the *acaca*, and the Angolan cornmeal porridge known as *funji* kept its name and its spelling as the dishes of the African continent were turned into Brazilian standbys.

African cooks embellished dishes with ginger, chilies, and pulverized cashew nuts and maintained the tastes of coastal Africa in the continued use of dried smoked shrimp and palm oil. They adapted recipes and adopted the ingredients of the new land to create a cooking so unique that the food of the state of Bahia is considered by many the linchpin that connects the cooking of Africa with that of the Western Hemisphere.

In the late nineteenth and early twentieth centuries, new immigrants joined the cultural mix that is Brazil: Japanese arrived to work on the coffee plantations, Syrians and Lebanese arrived and became shopkeepers and merchants, German and Swiss farmers settled in the

Brazil's long coastline has blessed it with a rich fish cookery. These fishermen are sorting their catch on the beach at Ceara, Brazil. © STEPHANIE MAZE/CORBIS.

southern states, and Italians established themselves in São Paulo. Each group brought its own dishes, and soon stroganoff and sushi, risotto and sauerbraten could claim pages in any Brazilian cookbook. The result is a country where the regional cuisine is as distinctive as it is varied.

### Regional Cuisines

The Amazon region still recalls the country's first inhabitants in dishes like *beijus*, cassava flour crackers that are sometimes flavored with coconut, and *pato no tucupi*, duck cooked with *tucupi*, a condiment prepared from cassava liquid with garlic, chicory, and the leaves of the *jambu* plant, which produce a slight numbing effect on the tongue. The condiment also turns up in *tacaca*, a soup that also contains dried shrimp and tapioca. Fish from the river abound, with the enormous *pirarucu* and the flavorful *tuncare*. Tropical fruits range from the little known, like the *guarana* (the seeds of which make a highly caffeinated beverage), *cupuacu*, a relative of cacao, and the fragrant *jambo*, or rose apple, to the more familiar *maracudja*, or passion fruit, and cashew. There are also Brazil nuts, called *castanha do para*.

Culinary historian Luís da Câmara Cascudo claims that the food of the country's northeast region can be broken down into that of Bahia and the rest of the region. The tastes of the rest of the region are simple ones, featuring dried meats called *charque*, *carne seca*, or *carne do sol*. Stewed with beans and served with rice and abundant sprinklings of cassava meal, the meals are as stripped of pretense as the cowboys and hard-scrabble farmers who inhabit the arid inland region known as the Sertao. The rich tastes of Bahia reflect the area's exuberance. The tastes of sugar, coconut, *cachaca*, chili, and orange-hued

The biodiversity of Brazil's native fruits is one of the largest in the world. These fruits were photographed in the market at Angra, Brazil. © Richard Bickel/CORBIS.

palm oil called *dende* abound in dishes where the African hand is evident. Dishes with the gustatory complexity of *vatapa*, a puree of dried, smoked shrimp, ground peanuts and cashews, bread crumbs, ginger, chilies, coconut milk, and palm oil, are popular. The *acaraje*, or black-eyed pea fritter, is traditional street food, often slathered with *vatapa*, and sweets prepared from coconut, sugar, and tropical fruits are traditional.

The two major cities of São Paulo and Rio de Janeiro revel in international dining that knows few borders, with restaurants owned by three-starred Michelin chefs and local notables. Specialties include Rio's Saturday *feijoada*, the country's national dish of black beans, rice, stewed meats, greens, and sliced oranges. São Paulo offers Japanese fare in the Liberdade district as well as German-style beer halls and *rodizio*-style churrascarias (Brazilian barbecue), where waiters circulate constantly with a never-ending procession of skewers of meat that is sliced at the table.

The heartlands of Minas Gerais and Goiás are marked by their love of beans. They celebrate with dishes like *Tutu a Mineira*, mashed black beans served with pork chops and kale, and a version of *feijoada* prepared with pink beans instead of black ones. Mineros pride themselves on their wood-burning ovens called *fogão de lenha* and their cheeses, which are prized throughout the country.

The southern states are more European in focus, with large settlements of Italians and Germans. They are

also the home of Brazil's gauchos and boast a meat culture centered on spit-roasting meat *churrasco*-style. The prairies of Mato Grosso and Mato Grosso do Sul are made up of huge ranches called *estancias* or *fazendas*, where cattle farming is a major industry. Beef, pork, and fish dominate the regional menu, and as settlement increases there, the newcomers are sure to add another chapter to the rich and ongoing history of the food culture of Brazil.

**BREAD.** What is bread? At its simplest it is merely a paste of flour or meal and water cooked over or surrounded by heat. More complex breads are leavened in various ways and contain salt and other ingredients, particularly fat and sugar. Although bread is usually thought of as being made from wheat, it can be made from virtually any grain—rye, corn (tortillas), barley and oats (bannocks), teff (injera), amaranth, millet, and rice. Only wheat, however, has the gluten that is essential to a risen loaf, so unless these other grains are mixed with wheat, the loaves will be flat. Many, such as oat, barley, and pure rye bread, will be heavy and dense as well.

### Plant Biology

The kernel of wheat is the grain used in most breads. Wheat is the single grain that contains enough gluten to allow the development of the protein strands that are the foundation of bread. These strands form layers and pockets that trap the steam from the water and the carbon dioxide released by the yeast during the fermentation process and thus give the bread its rise. Since other grains do not have this capability, they are usually combined with wheat flour to increase the gluten level of the mixture.

Wheat is not actually a seed but rather a true fruit. The wheat grain has three parts. Bran is the outer layer of the wheat kernel and is high in fiber and nutrients. The germ is the “embryo” of the kernel, and when sprouted, it reproduces new wheat plants. The endosperm makes up most of the kernel and is the food reserve for the germ. The endosperm is extracted during the milling process to make common white flour.

### Plant Nutrition

Wheat is rich in complex carbohydrates, which are an excellent source of energy for the human body. It also contains many essential B vitamins and the key minerals iron and calcium. After the milling process, in which the bran and germ, which contain most of the vitamins and minerals, are separated from the endosperm, enrichments frequently are added to the flour to restore the grain to its nascent nutritional levels. The two most common enrichments are folic acid, which prevents heart disease and neural deformities, and the other B vitamins, including niacin, thiamin, and riboflavin, which prevent beriberi, pellagra, and nutritional anemia.

### Types of Wheat

Many different types and strains of wheat are grown conventionally or organically worldwide. In the United States wheat is classified into four categories. Hard wheat is used for breads and similar baked goods; soft wheat is preferred for cakes and pastries; winter wheat, which includes hard wheat varieties, is planted in the late fall to over-winter in harsh climates and is harvested in the spring; and spring wheat is planted in the spring and is harvested in the late summer or early fall. Wheat is fur-

ther categorized as red wheat, that is, hard, red winter wheat; or white wheat, that is, soft, white spring wheat. The thousands of varieties of wheat grown in the United States break down into six classes: hard, red winter; hard, red spring; soft, red winter; durum, primarily used in pasta making; hard white; and soft white.

In the late 1990s the artisanal baking world developed an interest in wheat's particular profile. This profile is generally indicated by a farinograph, which displays such important factors as protein (gluten) levels, ash content (a measure of extensibility, related to fiber), and falling number. Each of these elements plays an important role in the overall baking process, and each farinograph number tells the baker what type of results to expect. The baker's knowledge of the specific flour's profile dictates how much water to add, how long to knead the dough, and how long the fermentation time should be.

Identity preserved (IP) wheat has also attracted interest. Traditionally, when the wheat is harvested, it is stored in large silos prior to distribution to the mill. The mélange of different strains of wheat, even within a single category, present in the silo makes it virtually impossible to know how the flour will perform once it is milled. Yet these “blends,” as they are called, are the most prevalent grains in the marketplace. Using the IP methodology, only one type of wheat is stored in a particular silo, thus giving the discerning baker more control over the outcome of the final product. While this IP methodology will probably never rule the marketplace due to silo space limitations and lack of general interest, it will continue to gain market share as the artisanal side of the baking industry continues to flourish.

### The History of Bread

It is widely believed that the domestication and cultivation of wheat and other grains directly influenced human transition from nomadic people to domesticated, stationary people. In most parts of the world this transition was completed as wheat and subsequently bread became significant dietary staples. However, people continued nomadic ways where cultivation of grains was either not feasible or not desirable.

The earliest breads were more like porridges and flat cakes. Grains were mashed with water or milk and were eaten either raw or cooked, providing nutrition and sustenance. The porridge became thicker and more paste-like, and eventually this paste was cooked either on a hot rock or in an early subterranean oven, creating a more mobile product. Twenty-first-century descendants of those earliest breads include Middle Eastern pita bread, Indian naan, and pizza.

The first leavened breads were invented nearly seven thousand years after flatbreads were introduced into the diet. To put the history of bread on a timeline continuum, it is necessary to start nearly ten thousand years ago. About 8000 B.C.E. the first grinding stone, called a

Bread is indeed the staff of life in most wheat-consuming countries. The great variety of North African breads is evident in this Tunisian bread shop. © MICHELLE GARRETT/CORBIS.

quern, was invented in Egypt, and the first grain was crushed. The modern Indian chapatis, made from unleavened whole wheat flour, and Mexican tortillas, made from corn, resemble the breads produced at that time. Between 5000 and 3700 B.C.E. Egypt began organized grain production along the Nile River Valley. At this time bread became a staple food that often was used in trade and barter, and it began to migrate to other cultures.

About 3000 B.C.E., also in Egypt, varieties of wheat that were tougher, that is, more tolerant of weather and environment, were developed. It is widely thought that, owing to the Egyptian skill with brewing beer and the warm climate, wild yeasts attracted to the flour mixtures created the first sourdough. Recognizing the fermentation process, bakers began to experiment and developed the first purposefully leavened breads. By about 2500 B.C.E. the first true sourdoughs were in regular production in the Middle East and Mediterranean regions.

In about 2300 B.C.E. the cultivation of grain began in India along the Indus Valley. Around 1500 B.C.E. horses took over the task of plowing and the first iron plowshares were introduced. In about 1000 B.C.E. yeasted breads became popular in Rome. The circular quern, the basis for milling until the Industrial Revolution and the

basis for so-called stone-ground flours in the twenty-first century, was developed by about 500 B.C.E. The water mill was invented in Greece around 450 B.C.E. Consequently culinary historians credit the Greeks with ushering in bread baking as an art form.

In Rome the first bakers guilds were formed as a means of unifying the craftspeople around 150 B.C.E. Well-to-do Romans insisted on the more exclusive and expensive white breads. Darker whole wheat and bran breads were for the masses, an attitude that persisted well into the twentieth century in Europe and North America. By about 100 C.E. Mexican natives made the first stone-ground corn tortillas. By 300 C.E. the Greeks had developed more than seventy different types of bread, showing their penchant for furthering the bread baking craft. Around 600 C.E. the Persians developed a windmill prototype that changed the face of bread production.

In medieval times bread baking became a status symbol in Britain. The upper classes preferred fine, white loaves, while those of poorer status were left with the whole wheat, bran, and coarser breads. By 1066 hair sieves were employed to sift the flour, producing a finer white flour. In 1569 in England, Queen Elizabeth I united the "white and brown" bread bakers to form the

Worshipful Company of Bakers. The Great Fire of London in 1666 reportedly was started by a baker. In 1683 the bagel was introduced in Vienna as a thank-you gift to the king of Poland.

Wheat was first planted in the United States as a hobby crop in 1777. During this century the earl of Sandwich gave his name to the sandwich, originally meat between two slices of bread. In 1789 mobs calling for bread helped trigger the French Revolution. In 1834 the roller mill was invented in Switzerland. Rather than crushing the grain as in stone-ground methods, the steel roller mill breaks open the grain, allowing easier separation of the germ, bran, and endosperm. This invention drastically changed milling around the world and increased the consistency of milled flour.

### Bread in Modern Times

Leavened bread was generally prepared outside the home, and this led to the development of communal bake houses. Usually situated by rivers or streams, these bake houses presented serious fire hazards due to the construction materials of the buildings and ovens. The proximity to water put them near the mills and close to natural fire suppression. Bake houses were usually owned by land barons and lords. Bakers and bakery owners used the ovens on a communal basis for a fee paid either in money or in kind. The very nature of the bake house allowed bakers to bake more bread, thus increasing their ability to distribute it and keep prices down.

The same innovations of the industrial revolution that made white wheat breads more plentiful also made mass production the norm. By 1825 German bakers created the first cakes of commercial yeast, which expedited the process and consistency of yeast activity and influenced taste and visual appeal as well. In the twentieth century hydrogenated oils, artificial preservatives, emulsifiers, and other chemical additives entered the dough to soften the crumb (texture) and to lengthen the shelf life of mass-produced breads. Factory bread has become standard in most industrialized countries.

By the early twentieth century bread flour was largely replaced by bleached, bromated, and enriched flour. The grain is bleached and sterilized with chemicals to make it white and soft. It is then enriched by adding back the vitamins and minerals destroyed in the processing. Obviously this industrialization of bread methodology and production altered the taste and appearance of bread. Some authorities feel this methodology is largely responsible for the mid-century decline of bread consumption in the United States. In 1910 the per capita consumption of bread products was roughly 210 pounds. By 1971 consumption had been cut nearly in half, to approximately 110 pounds per person. This trend turned around with the rediscovery of artisanal breads and methodologies. The trend back to more wholesome and historical breads began in the United States in the 1980s. Some bakers who wanted to be more mindful of the

As bread baking became industrialized during the nineteenth century, professional bakers turned to baking aids like this cream loaf pan of tinned sheet iron, which simultaneously makes six large sandwich “batons.” The loaves are perfectly round for slicing. Manufactured about 1890 by Thomas Mills Brothers of Philadelphia. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

process and their ingredients returned to their baking roots. They produced freshly baked, wholesome, rustic breads that benefited from longer fermentation periods, and they eschewed all chemicals and additives. The result is a more flavorful and nutritious loaf similar to those baked over a thousand years ago. Led by the Bread Bakers Guild of America (modeled after the first European bakers guilds) this reinvention of bread permeated baking cultures throughout the industrialized world.

### Buying Bread

By the twenty-first century bread products were sold on three major levels. The first is the traditional neighborhood bakery, still in existence in large urban centers in the twenty-first century. The second is the grocery store, or supermarket. Third is what might be called the bakery café, along with the specialty foods store.

**The neighborhood bakery.** The neighborhood bakery has its roots in western Europe and is known for its local roots and outreach as well as the freshness of its products. This is particularly true in France, where local boulangeries are numerous. Each one offers local residents their daily bread, fresh, uncommercialized, and unique to that particular bakery.

Local bakeries build their client base from the immediate neighborhood, especially in larger urban centers, where population density and foot traffic allow the independent baker to make a living by directly connecting to his or her customer. Breads are baked fresh daily and are

meant to be consumed that day or the following day at the latest. Even though, as a result of the extended fermentation used, many of these breads have a longer shelf life than one or two days, it is the freshness that sells the bread.

**Grocery stores.** The amount of bread purchased at grocery stores and supermarkets is the largest portion by far primarily because of the convenience of one-stop shopping. These bread products have been developed and baked with a longer shelf life in mind than breads baked in a neighborhood bakery. Frequently made with dough conditioners, emulsifiers, and mold inhibitors, they are meant to withstand plastic bags and to last for several days in the store.

In general the types of breads found in the grocery store are a result of the bread industrial revolution that took place at the beginning of the twentieth century. Consumer desire for white bread with a soft crust along with mechanized developments in the milling and baking industry made it possible not only to mass produce a homogeneous product but also to distribute it over a wide geographic area. While exceptions exist, most of these factory-produced breads have taken a formula detour from similar products produced in neighborhood bakeries. Dough conditioners make it easier for the wholesale bakery's machinery to handle the dough without damaging it and to soften the crumb of the bread. Emulsifiers homogenize the dough (in some cases it is nearly batterlike) so each loaf of bread resembles the ones before and after it. Mold inhibitors are used in the actual formula and are sprayed topically as the bread exits the oven to delay the onset of bread mold.

Bakery departments have also been created in the grocery store itself to reach the customer who wants a fresher product. Breads are baked throughout the day, and in addition to being fresher they generally have a more pronounced flavor. Where the baker gives care and attention, the in-store product can come close to the quality of breads produced by the local neighborhood bakery. However, when the baker is working from a base or mix or even with a par-baked product (a frozen, partially baked bread that is finished off in the store), the overall quality is usually only a slight improvement over the bread on the store's shelves.

**Bakery café and specialty foods stores.** Bakery cafés and specialty food stores have experienced widespread growth since the early 1980s. Both typically provide a higher-quality product than that found in the grocery store. Whether purchased from a high-quality wholesale bakery or baked in-house from a fresh or par-baked product, baked goods comprised a wide selection.

### **Bread Preparation: Yeasted Dough**

Yeast dough production requires twelve basic steps no matter what type of dough is produced. Dough types are generally classified as lean dough (low in fat and sugar), including French baguettes, rustic breads, Tuscan breads,

hard rolls, and pizza; rich dough (with sugar, fats, or eggs added), including brioche, challah, and egg breads; and rolled-in dough (with fat incorporated in many layers using a rolling and a folding procedure), including croissants, Danish pastries, and cinnamon rolls.

### **The Twelve Steps of Yeast Dough Production**

Scaling is the exact measurement of all ingredients (professional bakers and dedicated amateurs measure by weight) and the French term, *mise-en-place*, applies to having all the ingredients scaled or prepped and ready before starting production.

Mixing and kneading involve the incorporation by hand or by machine of the ingredients in proper sequence to form the bread dough, which is then further kneaded. Kneading or working the dough by hand or by machine further disperses the ingredients and develops the gluten in the dough.

Fermentation, also referred to as the first rise, is the process whereby the gluten (protein) in the dough is allowed to relax while the yeast grows and reproduces. The yeast digests the sugars in the flour and produces alcohol and carbon dioxide (CO<sub>2</sub>). The carbon dioxide gets trapped in the pockets that result from the kneading process and causes the bread to expand or rise and develop flavor. At this point the dough can be left at room temperature if it is to be baked that day, or it can be retarded; that is, the fermentation period can be extended in a cool environment, usually a specialized refrigerator. Doughs that have been retarded for twelve to twenty-four hours generally have more complex flavors and are easier to fit into the baker's production schedule. There is also a noticeable buildup of natural acidity, which helps extend shelf life.

Punching down or deflating the dough, also called turning, refers to the general deflating of the dough mass by either gently pushing down or folding the dough, not hitting it as implied. The purpose is twofold, to increase the strength and tolerance of the gluten and to de-gas the dough prior to scaling. After punching, the dough is allowed to rest before moving on to the next step.

Scaling is cutting and weighing individual pieces of dough, which will become the actual loaves of bread.

Rounding occurs once the dough has been scaled. Each piece is gently shaped into a round ball before moving on to the next step. This rounding allows uniformity in subsequent steps.

Benching is allowing the dough pieces to rest, usually for fifteen to twenty minutes. The time varies with each type of bread and with the amount of leavening used. Clean, dry towels placed over the dough during this period prevent a dry crust from forming on the dough.

Make-up is forming the individual pieces of dough into their final shapes, free-form loaf, pan loaf, dinner rolls, and so forth.

Proofing, also referred to as the final rise, allows the dough to rise one last time before baking. The yeast is still alive and continues to leaven the dough. Proofing generally takes place in a warm, draft-free environment either at room temperature or in a proof box, where temperature and humidity are controlled. At this point shaped loaves can be retarded for twelve to twenty-four hours and baked at a later time.

Baking is the actual cooking of the bread. When the dough is put in the hot oven, it undergoes oven spring, one last push of the yeast to make the dough rise. The actual temperature and time depend on the oven type (deck, rotary, convection, rack, and so forth) and the use of steam, although yeast breads are generally baked at a high temperature. Technically speaking, this is when the starches gelatinize and sugars caramelize, giving the loaf its final appearance.

Cooling begins when the finished bread is removed from the oven. The bread cools completely before it is packaged or sliced. Cooling racks are usually nothing more than wire shelves that allow air circulation on all four sides of the bread. Even breads baked in or on pans are quickly removed to a cooling rack so the bread bottoms do not become soggy from continued steaming.

Storing prevents the staling or starch retrogradation that begins as soon as the bread is removed from the oven. To preserve their thin, crisp crusts, some breads are best not packaged (lean breads in particular), but modern baking and distribution practices require many bakers to do so. Once a loaf has been put into a bag, the staling process is somewhat slowed down and the crust becomes soft. Wrapping and freezing help maintain quality for a longer period of time. Refrigeration, on the other hand, speeds up staling.

### Methods of Preparation

While the twelve steps of baking are virtually constant for almost any bread form, three predominant production variations exist. Each is a means of manipulating the key ingredients to produce a predictable loaf of bread. Production timing is also influenced. The key difference is fermentation, the natural process that occurs after the ingredients have been mixed and the dough has been kneaded. The length of fermentation time has a significant effect on the overall flavor profile, on the end product, on the baker's production life.

**Straight dough method.** The straight dough method is perhaps most familiar to all bakers, professional and amateur alike. It incorporates the twelve steps in a direct fashion as dictated by the ambient temperature of the bakeshop, proceeding through the steps with no break. The total time of the cycle would be about four hours from start to finish. Because of the relative shortness of the baking cycle, a higher proportion of yeast is used than in other methods so that fermentation can run its full course. The result is a bread with a stronger yeast flavor than other breads.

In its most rustic form, bread was often baked in the hot ashes of a fire, hence the term “ash bread” or “ash cake.” This cattle hand in Pugal, India, has just baked flat bread on a giddle over a small fire. © ZEN ICKNOW/CORBIS.

**Sponge method.** The sponge method follows the same twelve production steps with a few exceptions. Initially a percentage of the total flour, water, and yeast are mixed to form a sponge or pre-ferment. The sponge method enhances the flavor profile of the final product. Since less yeast is used, a longer, cooler fermentation can be applied, ranging anywhere from three to twenty-four hours. During this time the lactic acid bacteria in the water-flour mixture have full time to develop. The resulting buildup of organic acids and alcohols contributes to a more developed flavor profile. When the sponge is ripe, it is incorporated into the remaining flour, water, salt, and other ingredients. The twelve steps are followed from this point on.

**Typical pre-ferment types.** Poolish, one of the first pre-ferments made with commercial yeast, originated in Poland and is widely used by French bakers. Made with a higher percentage of water as opposed to flour than other pre-ferments, poolish has a batterlike texture. Biga,

a pre-ferment of Italian origin, is more doughlike than a poolish and is commonly made with equal parts (by weight) of flour and water. Old dough is a piece of dough from an earlier batch of bread that is allowed to ferment and then is incorporated back into a fresh batch of dough. Called *pâte fermentée* (fermented dough) by the French, it can be fermented for up to six or eight hours at room temperature or longer under refrigeration.

Sourdough uses wild yeast to build a culture. Wild yeast, the flora, is present in the air and on the skins of fruits and vegetables. The baker basically harvests those wild yeast organisms and creates a culture that will leaven bread dough.

First, a culture is created using water and flour. This mixture is left covered with cheesecloth or another porous material at room temperature until it begins to ripen. At this point, the wild yeasts, having found the food (primarily natural sugars) in the flour, begin to feed and reproduce. A slightly acid smell and bubbling indicate that the culture is alive. The culture is continually fed to increase its volume and leavening strength until there is enough starter (*levain*) to leaven a batch of dough with enough left over to perpetuate the culture. Under the right conditions, cultures can be kept vital and alive for many years. The sourdough method is a time-intensive method, since no commercial yeast is used to speed up production. The benefits are many, however. Due to the lower yeast levels, the slower activity produces a stronger flavor profile and more noticeable sour aroma, an increased level of organic lactic acids, and a greater array of naturally occurring bacteria. It is primarily due to the abundance of naturally occurring acids, alcohols, and bacteria that breads baked with the sourdough method become stale more slowly, have a better shelf life for the vendor and the consumer, and have less molding.

### Traditions: A Historical Perspective

Bread and traditions pertaining to it are deeply ingrained in lore and language worldwide. From its beginnings bread has held a special, even sacred sway on humankind. As bread is the staff of life, it is truly all-pervasive.

Challah is the Jewish bread served on the Sabbath and on holidays in which the twelve tribes of Israel are represented by twelve braids on each loaf. For Rosh Hashanah, the Jewish New Year, the challah is wound in a ring to symbolize the continuity of life. Some loaves have a ladder on top, representing the ascent of God on high.

According to legend, a baker alerted the forces of Vienna to the approach of the Turks in the siege of 1683. The bakers commemorated the Viennese victory with a crescent-shaped roll, precursor to the croissant, as the symbol of the Turks was a crescent.

In France a law prevented bakers from increasing the price of bread beyond a point justified by the price of the raw materials. Tuscan bakers, during the time of papal

dominance, were subjected to an extremely high salt tax. As a result Tuscan bakers decided to abolish salt in their breads. Tuscan tastes adapted to this custom, and a traveler will note, for example, that Tuscan prosciutto is considerably saltier than its regional counterparts.

Several cultures celebrate the Epiphany (6 January) with a ring cake with a tiny doll representing the Christ child baked in it. Whoever gets the piece with the doll is crowned king or queen for the day and is obliged to reciprocate by giving a party on Candelmas (2 February).

### Bread in the Lexicon

Bread has been a part of language for many thousands of years. Because of the importance of bread worldwide, it should come as no surprise that bread talk has permeated the everyday vocabulary. In 1933 nearly 80 percent of the bread sold in the United States was sliced. The expression “the best thing since sliced bread” was coined from this market predominance. The term “break bread,” meaning to dine together, highlights the reverence given to bread and its importance at mealtime.

The expression “bread upon the water” describes resources risked without expectation of return. Bread was a form of currency in ancient Egypt, and the term “bread” is colloquially used as a term for money. “Breadwinner” designates the person who earns the better part of the household income.

Bread has long been called the staff of life. This metaphor of the wheat stalk expresses the importance of wheat, grains, and in turn bread. The term baker’s dozen refers to a count of thirteen, rather than to twelve, a traditional dozen. Dating back to the Middle Ages, some bakers cheated with undersize and occasionally adulterated loaves. An extra loaf or item was thrown in to reduce suspicion.

### Bread and Human Biology

Bread is a great source of energy because it is rich in complex carbohydrates. The human body slowly turns these carbohydrates into sugars, which the body utilizes for energy. Breads and grain products occupy the first and largest rung of the widely accepted Food Pyramid. The Food and Drug Administration (FDA) has indicated that all adults should eat six to eleven servings of carbohydrates daily (depending on age and gender), and bread can make up a large segment of this daily intake. As approved by the FDA and the U.S. Department of Agriculture (USDA), breads rich in whole grains can advertise that they help fight heart disease and cancer. Breads (and grain-based foods in general) that contain 51 percent or more whole grain ingredients by weight can use the following health claim on labels: “Diets rich in whole grains and other plant foods low in total fat, saturated fat, and cholesterol may reduce the risk of heart disease and certain cancers.” Whole grain breads are also a great source of fiber and roughage, which aid the body’s digestive and waste elimination systems.

Grain products are enriched with iron, folic acid, and other B vitamins, including niacin, thiamin, and riboflavin. Over the years enrichment has helped eliminate nutrition-related diseases, such as beriberi, pellagra, and severe nutritional anemia. Research has shown that folic acid helps prevent heart disease. Women of childbearing age also need folic acid. The daily minimum requirement of four hundred micrograms is essential in preventing birth defects of the spinal cord and brain.

Peter S. Franklin

**BREAD, SYMBOLISM OF.** Bread is among the most popular foods in the world. Whether it is leavened or unleavened, made into loaves or cakes, baked, steamed, or fried in oil, bread is universal. Whatever the grain, bread occupies an important place in every civilization.

It has exceptional nutritional value, and as the only nearly perfect product for human nourishment, can be consumed by itself. It is made from flour, water, salt, yeast, and sometimes additives.

Farming has had a profound affect on the religious beliefs of agricultural communities, and the symbolism of wheat is deeply associated with the symbolism of bread. Since the Neolithic period, mythology and ritual representation have tended to be identified with plant life because the mystery of human birth and death was in many respects similar to the life cycle of plants.

The growth of settlements, which ethnologists refer to as the "great turning point for humanity" and which was indirectly inspired by the search for bread (agriculture was only a means to this end), helped define social and economic institutions (the growth of property rights, the use of wheat as a form of exchange value, and so on). Planting and harvesting as well as the events that endanger crops (flood, drought) were perceived as key events in agricultural life.

During its life cycle the grain of wheat dies and is reborn months later in the form of a spike capable of providing sustenance to human beings. Wheat is the quintessential nutritional plant. It was believed to contain the mystery of life and death and thus it became a sacred plant. One of the essential features of the Neolithic era was plant cultivation. This led to a way of life that had previously been unimaginable and gave birth to new beliefs that completely altered the spiritual universe of humankind.

Religious connections with the animal world were replaced by what might be called a mystical solidarity between humankind and vegetation. Moreover, female sacredness and the female principle in general assumed greater importance because of women's influential role in agriculture. Women's fertility was associated with that of the earth, and women were responsible for the abundance of the harvest because of their knowledge of the mystery of creation. During the fertility festivals in Syracuse (Sicily), loaves of sesame bread shaped like female genital organs were handed out.

This sacred and divine dimension of the wheat spike helped associate it with the symbolism of resurrection. Examples survive on bas-reliefs from the temple of Isis, the Egyptian nature goddess and wife and sister of Osiris, in Philae, an island in the Nile, in which the mummy of Osiris, god of the underworld, presents spikes of wheat watered by a priest, symbolizing the new wheat that will soon grow. This same symbolism is found on clay statuettes of Osiris that contain wheat kernels, which were placed in graves to ensure the survival of the dead.

This close relationship between the celebration of the seasons, the death and rebirth of the god, and the possibility of a life beyond the grave clearly illustrates the connection between wheat and Osiris and the manifest symbolism of resurrection, which he represented in

In this 1883 promotion for Wonder Flour (the ancestor of Wonder Bread) the lightness of the bread is weighed against an ostrich feather, implying that airy bread from processed flour is better than the old hearth-baked kind, a point most artisanal bakers would dispute. The flirtatious woman in red, white, and blue, dressed like a cancan dancer, would have raised eyebrows with her leg-exposing attire. The second implied message, then, is that light bread is sexy. ROUGHWOOD COLLECTION.

Egyptian religion. Ancient Egypt was far from unique, however, for cereal plants were associated with divinities in nearly all cultures, such as the Greek goddess Demeter and the Roman goddess Ceres.

In the Old Testament wheat and bread are symbols of the fecundity of the earth. The New Testament associates the fruits of the earth—a gift of God to humankind—with the symbolism of wheat and associates the gifts of God with the hearts of humans (grace), especially in the parable of the good seed and the bad seed. Bread becomes the symbol of the supreme gift from God to humankind—eternal life, the body of Christ in the Eucharist: “Take this and eat, for this is my body.”

In Hebrew “Bethlehem” means ‘house of bread’. The city is located seven kilometers (five miles) south of

Jerusalem and is considered the place of origin of the house of David and the birthplace of Jesus. In the Old Testament the Eternal sends manna to the Hebrews when they are crossing the desert (Exodus). Manna symbolizes bread and prefigures the Christian Eucharist. It is a sign of the generosity of God toward humankind. Jewish matzoh is an unleavened bread that is eaten to commemorate this event. In the Roman Catholic faith, unleavened bread is used to prepare the hosts for the Eucharist. The Orthodox Church uses leavened bread.

In imperial Rome bakers (*pistores*) celebrated 9 June, the Vestalies, in honor of the Roman goddess Vesta. In the *Fastes* the Roman poet Ovid describes how the Romans came to worship Jupiter Pistor or Jupiter the Baker. According to Ovid, when the Gauls attacked Rome in 387 B.C.E., the Romans invoked Jupiter, and the great god counseled them to throw what was most precious to them over the walls. While praying to Ceres, they prepared small loaves of bread with the remains of their flour and threw the loaves at their assailants. Seeing this, the Gauls believed Rome was well provisioned and had the wherewithal to withstand a lengthy siege, so they abandoned their assault of the city. In recognition the Romans built a temple to Jupiter Pistor that associated the symbolism of wheat (life, death, and rebirth) with the destiny of the city.

Bread is not associated only with spirituality and the afterlife, however. Even in antiquity the production of bread was associated with procreation. The process of loading, baking, and unloading the oven parallels copulation, pregnancy, and childbirth. In Hebrew and Chaldean the word *zera* has several meanings referring to the seed of the plant, to sperm, and to human progeny. Hebrew *zera* became the Greek *sperma*, Latin *semen*, and English “seed.” Latin *placenta* was the name of a much appreciated pastry served on feast days in ancient Rome. Leaven, which plays the role of the grain or seed, is also referred to as “mother” in English and *madre* in Spanish. In Egypt the basket in which dough is left to rest is known as a *coffin*. Various popular expressions associate bread with the concept of procreation. In France a young woman who found herself pregnant before marriage was said to have “borrowed a loaf from the batch.” In England the expression “a bun in the oven” refers to a woman’s pregnancy. Bread symbolizes the forces of life, and an element of eroticism is associated with its manufacture. The French word *four* (once *for*) for oven is derived from church Latin *fornicatio*, in turn derived from *fornix*, which literally meant a vault but figuratively meant a prostitute. In ancient Rome, prostitutes fornicated with clients in vaulted rooms that resembled ovens.

The French word *miche*, used for a round bread loaf, also signifies breast or buttocks, and a *bâtard* is a thick French baguette. In English buns refer to the buttocks as well as various small round rolls. In Italy, in the region around Naples, a small bread loaf is known as an “angel’s penis,” and in Germany *Brotleib* can refer to the female body.

While bread is itself a symbol of life, shaped breads carry multitudes of additional meanings. One of the oldest shaped breads is the ring shown here in an Athens market. This is the *bracellus* of ancient Greece and Rome, a form of bread associated with abstinence and even death. In the oldest surviving manuscript of the *Aeneid* (sixth century C.E.), Aeneas and Dido are shown breaking a *bracellus* prior to her self-immolation. © NEIL BEER/CORBIS.

The sickle is often associated with wheat and bread because of its role in the harvest, but it is also associated with the god Saturn, the mistletoe of the Druids, and the silver bow that belonged to Artemis, the sister of the sun god Apollo. That is why, in connection with grain, the sickle fulfills one of the functions of the moon, for the harvest ends a life cycle that begins with the death of the kernel of wheat. Like the scythe, the sickle serves as a positive end to the cycle for it signifies the harvest and nourishment, both physical and spiritual. It also prefigures the symbolism of wheat, the bread of the future, and other promises of transformation.

Bread is an object of belief and superstition in many cultures. The Hittites believed that the bread served to soldiers preserved them from impotence and that leavened bread helped ward off epidemics (providing it was placed in a special barrel). In Belgium during the Middle Ages, bread kneaded on Christmas Eve protected the home against lightning. In many places people give newlyweds bread and salt to express the hope for health and prosperity. In Russia a saltcellar is placed on top of the loaf of bread, which is presented to the couple by one of their mothers.

Many other ancient beliefs have continued into the twenty-first century. In Sweden it is customary to prepare a flat round bread pierced with a hole when a daughter is born, and the bread is eaten the day she gets married. In Hamburg, Germany, a highly suggestive, triphallic

bread is offered to the bride and groom on their wedding day. For centuries Christians have made the sign of the cross on the crust of a loaf of bread before cutting it.

Throwing bread out or placing it upside down on the table supposedly brings bad luck. This superstition is connected to an ancient belief that bread turned toward the entrails of the earth, therefore toward hell, attracts evil spirits. In another medieval belief, bakers refused to have any physical contact with or even to serve the executioner of Paris, a man who inspired fear and was held in contempt by the people of the city. Ultimately the king was forced to issue an edict that compelled the bakers to serve the executioner. In protest and as a sign of their dissatisfaction, the bakers turned the executioner's loaf upside down on the rack to distinguish it from the others.

Various powers are attributed to bread blessed by a priest. At the end of the feast in honor of Saint Joseph in Sicily, guests are sent home with a piece of consecrated bread to keep in the house to bring fertility and good fortune in the coming year. On the Feast of Saint Calogero, Sicilians bring ex-votos made of bread covered with poppy seeds to church to be blessed. Islanders keep consecrated bread to throw upon the stormy waters for the safe return of fishermen at sea. *Kulich* (Russian Easter bread), a domed cylindrical loaf, is decorated with religious Easter symbols (notably *XB* for *Khristos Voskrese* or Christ is Risen), surrounded with dyed eggs, topped with a beeswax candle, and taken to church to be blessed.

According to popular belief, the sign of a perfectly baked *kulich* is that it will never mold; some say it will last for a year. *Kulich* is shared with the departed when, on Easter Monday, families go to the cemetery to picnic on the gravesites. In Russia true *bliny*, yeast-based pancakes prepared only once a year during *Maslenitsa* or Butter Week (Mardi Gras), represent the sun—round, golden, and warm—and symbolize the arrival of spring. One is always left in the window for the departed.

*Kutya*, a sweetened wheat-berry pudding, is traditionally the first or last food eaten on Christmas. Though more of a porridge than a bread, *kutya*, which is decorated with a cross of almond slices on top, is taken to gravesites or even thrown into the open grave. It is also given to propitiate Father Frost. *Kutya* bears an uncanny resemblance to *cuccia*, a Sicilian wheat-berry pudding served on the feast of Saint Lucy, when traditionally no milled grain is eaten. (Saint Lucy was a blinded martyr, and under the Julian calendar her feast day was on the darkest day of the year, the first day of winter; it is celebrated on 13 December under the Gregorian calendar.)

For centuries bread has been a formidable political and economic weapon, and from ancient Rome onward, those in power have always kept a watchful eye on its availability. Roman bakers, for example, were closely regulated and under the control of the state. The Roman state went so far as to nationalize the baking industry. In France over a millennium and a half later, repeated famines triggered the French Revolution. Napoleon's letters during his campaigns attest to the emperor's extreme preoccupation with the supply of bread to Paris. The weight and price of bread was still regulated by the state in France in the twenty-first century.

Ancient breads have been a source of inspiration. They are a rich trove of ideas for bakers in the twenty-first century. While the techniques for making bread have changed, the human stomach has not. Industrial methods of production and freezing have led to the creation of new bread types, but industrially produced bread will never replace artisanal bread, which has undergone something of a renaissance in the United States in the early twenty-first century. The new gastronomy emphasizes quality much more than quantity.

A symbolic foodstuff international in scope, bread is the quintessential human food. Its history underlies a large part of the history of the human race, the simplest perhaps in the history of everyday life and eating. It connects people to culture, to tradition, and sometimes to religion.

**BREAKFAST.** Breakfast, the first meal of the day, can mean many things to many different people. The English term comes from a Middle English word meaning 'breaking the fast'. Any meal that breaks the overnight fast that occurs while we sleep is considered "breakfast."

#### Breakfast throughout History

From archaeological evidence at Neolithic sites we know that there was an early reliance on cereal grains; what people consume at breakfast, however, has changed considerably over time and place. Wild emmer and einkorn wheats and a variety of barley were first gathered and then cultivated in the Middle East around 7000 B.C.E. (McGee, p. 233). Maize (corn) was grown in South America and rice in Asia starting around 4500 B.C.E., and rye and oats were cultivated in Europe from about 400 B.C.E. Neolithic peoples used stone querns to grind the hulled grains, then boiled them to make a kind of porridge.

Roman soldiers woke up to a breakfast of *pulmentus*, a porridge similar to the Italian polenta, made from roasted spelt wheat or barley that was then pounded and cooked in a cauldron of water. On the march, they ate *bucellatum*, dried bread similar to Holland rusk (Renfrew, p. 22). People in the Middle East made and grilled flatbreads of all kinds, perhaps accompanied by green onions or another easily cultivated vegetable and a soft cheese, a tradition that carries through to the present time.

When other types of wheat were introduced throughout the Middle East and Europe, higher-rising breads could be baked. Only the wealthy could afford wheat bread because the cultivation of wheat required the most fertile lands. Oats and barley could grow in poorer soils and a colder, wetter climate and provided the basis for heavy breads that peasants ate. Barley was also used to make malt and thus to brew beer from Neolithic times onwards. Water was regarded as unsafe to drink from ancient times through the Renaissance, so beer was the beverage of choice for breakfast. People living in what is now Europe broke their fast with a mug of beer and an oatcake, a heavy bread made from barley and oats, or a bowl of porridge.

In warmer climates, rice became a breakfast staple. In Hong Kong, chicken *congee*, or rice cooked in a rich chicken stock, has been eaten with tea for breakfast for centuries. Likewise in southern India, rice is cooked with fresh ginger, chilies, and spices and served with eggs cooked in ghee or clarified butter.

In South America, maize kernels were soaked in lime to remove the hulls and then ground into a moist *masa* to make corn tortillas—the flatbreads of South America. These are still served with eggs, salsa, refried beans, plantains, avocados, and spiced pumpkin seeds or pepitas and other accompaniments for breakfast.

By the end of the 1600s, breakfast throughout most of Europe and the American colonies was a simple affair similar to the current “continental breakfast” offered in hotels in America and Europe. Less affluent households still drank beer for breakfast with their bread or porridge, but wealthier households began to include coffee or tea. Bread and butter, a selection of cold meats, perhaps porridge on a cold day, and coffee, tea, or another hot beverage was the breakfast norm by the early 1800s. In 1821, English writer William Cobbett complained in *Cottage Economy* that “The drink, which has come to supply the place of beer, has, in general, been tea. It is notorious, that tea has no useful strength in it; that it contains nothing nutritious; that it, besides being food for nothing, has badness in it, because it is well-known to produce want of sleep in many cases, and in all cases, to shake and weaken the nerves.” England imported 20,000 pounds of tea in 1700 and 20 million pounds by 1800.

Arabs in Ethiopia had been cultivating coffee beans and making the dark, rich beverage since 1000 C.E. Coffee traveled to Turkey, then, by the 1500s, to Venice as part of the spice trade, where it was discovered by the English. Enterprising planters smuggled coffee beans to create plantations in the East Indies and later in South America. By the mid-1650s, coffee was the main attraction at cafés, named after the French word for coffee, in London and Paris. Today, coffee and tea remain breakfast fixtures all over the world.

By Victorian times, when abundance was enjoyed by Americans as well as the British at the height of the British Empire, breakfast was a lavish affair, whether served at a table in a farm kitchen or in an elegant city dining room. Cookbooks from the period provide insight into the breakfast served by affluent households. In the 1861 *Book of Household Management*, Isabella Beeton suggested a daily breakfast buffet that included a cold joint of meat, game pies, broiled mackerel, sausages, bacon and eggs, muffins, toast, marmalade, butter, jam, coffee, and tea.

In the 1877 *Buckeye Cookery and Practical Housekeeping*, the anonymous American compilers suggested breakfast menus for every season. In spring, they recommended fried brook trout, eggs on toast, baked beans and Boston brown bread, rice waffles, coffee, tea, and milk. In summer, the menu included fresh Nutmeg melons, fried fish,

Photographer Michael Neveux has played visual games in this picture called “Balanced Breakfast,” which tosses a humorous volley at both nutritionists and gravity. © MICHAEL NEVEUX/CORBIS.

Saratoga potatoes, and sliced tomatoes. The fall menu called for oatmeal mush, fried salt pork, corn oysters, baked potatoes, and stewed peaches. In winter, the recommendation was for pork tenderloin, fried apples, buckwheat cakes with syrup, and sliced oranges.

During the nineteenth century, cooks also made breakfast dishes that were a combination of cereals and meats. Scrapple, a blend of pork and cooked cornmeal mush, is sliced and fried for breakfast in Pennsylvania. In Cincinnati, breakfasters still love *goetta* (pronounced “get-uh”), a savory blend of cooked whole oats with pork and onions, also sliced and fried. At this same time, there was a movement against these lavish eating habits, which resulted in the birth of the breakfast cereals we are familiar with today. On 25 December 1865, Ellen White had a vision at her home in Battle Creek, Michigan. She saw the ailing members of her husband Elder James White’s congregation returned to blooming health and was convinced that a better diet consisting of more whole grains and fiber was the missing component. And since Battle Creek was the national headquarters for the Seventh-Day Adventists, the Whites’ religious affiliation, she wanted all Seventh-Day Adventists to be restored to health. She persuaded her husband to offer a medical

scholarship to John Harvey Kellogg, who then set about studying nutrition in New York City.

As a student who wanted a healthier diet, Kellogg cooked for himself and knew how long it took to first soak and then cook whole or cracked grains. He wanted an easier way to eat a nutritious breakfast, and the idea of precooked cereals came to him. However, it took two years of trial and error before he introduced the first ready-made cereal—"Granola," as he called it—to the patients at the Seventh-Day Adventist health sanitarium in Battle Creek. Soon to follow were Grape-Nuts, so named because they were sweetened with dextrose or grape sugar and the product had a nutty flavor, in 1898; they were developed by Dr. Kellogg and his brother Will. Corn flakes flavored with malted barley debuted in 1902. Alexander P. Anderson of the Quaker Oats Company developed the technology for puffed cereals, and puffed rice was introduced to the American consumer at the St. Louis World's Fair in 1904. Today, 66 percent of Americans still eat cold cereal for breakfast (Perryman). Even those who skip breakfast still might drink a glass of orange juice, another breakfast staple.

### Breakfast around the World

Americans also enjoy other types of breakfast foods, some more healthy than others. In addition to fruit juices, particularly orange juice, pancakes, biscuits, eggs, bacon, sausages, and other breakfast meats, Americans also consume hash brown potatoes and breakfast pastries such as coffee cakes, donuts, and muffins. About 7 percent of Americans enjoy a Southern-style breakfast with eggs, sausage, grits, and biscuits. On-the-go breakfasters—now about 68 percent of the population—might stop at a fast-food restaurant for a cup of coffee, a breakfast sandwich, a bagel, or a doughnut. Fast-food restaurants have expanded their breakfast offerings while the number of bagel emporiums and coffee shops has greatly increased to meet the growing needs of these breakfasters on the way to work or school. Health-conscious eaters favor breakfast cereal bars, plain bagels, yogurt, and herbal tea or fresh-squeezed carrot juice, and have prompted this segment of the prepared foods market to burgeon (Lach). About 32 percent of Americans currently eat toast for breakfast.

Unlike the sit-down family breakfast of the past, the early-twenty-first century American breakfast is eaten at different times before parents and their children leave for work and school. This trend also fuels the need for easy-to-eat breakfast items such as breakfast bars, yogurt, cereals, toaster pastries, and microwavable frozen breakfast entrees.

In England, the typical English breakfast or "full fry-up" includes fruit juice, a bowl of cereal, eggs with fried streaky bacon or sausages, sometimes grilled tomatoes and mushrooms, perhaps a kipper or other smoked fish, fried bread or toast or scones, and marmalade. In France, a croissant or a baguette with fresh butter and a cup of

*café au lait* (coffee with milk) is common. Italians enjoy a light breakfast of pastry or bread and butter with coffee, while the Germans, Swiss, Dutch, and Scandinavians prefer a breakfast of cold sliced meats and cheeses, bread and butter, jam, and perhaps a boiled egg. Dutch and Belgian breakfasters might enjoy a touch of chocolate—as a filling in a croissant or chocolate sprinkles known as *bagel* over buttered toast.

In other parts of the world, breakfast is equally simple. In India, it might mean flatbread with cardamom-scented tea or steamed dumplings with a spicy sauce and coconut chutney (Sahni, p. 104). Mexicans eat *huevos rancheros*, or scrambled eggs with chilies and salsa, or even *menudo*, braised tripe, and burritos. In Saudi Arabia, families eat eggs, baked beans, cheese, olives, and *ma'soub*, or pancakes with bananas, but are also including American cereals.

### Breakfast as a Social Ritual

Apart from the necessity of breaking the fast, the first meal of the day can also function as an important social ritual. Retired businessmen and farmers, networking men and women in management, mothers of young children, or singles often meet at a designated restaurant for an early morning breakfast. Schools, churches, and other organizations offer pancake breakfasts as fundraisers. Tailgate breakfasts served from the back of a car or van feed fans at weekend football games; hunt breakfasts served buffet-style feed those about to saddle up.

The wedding breakfast, a more formal affair, brings together the wedding party and the families for an elegant first meal to start the couple's big day—or, often, their first day as a married couple on the day after the wedding. Less hearty foods, such as champagne, smoked salmon, shirred eggs, eggs Benedict, steamed asparagus, and Danish pastries would be on a wedding breakfast menu.

Brunch, a combination of breakfast and lunch served later in the morning, is often a relaxed social occasion, most often held on Sunday in private homes or restaurants. Savory bread puddings, egg casseroles, omelets, waffles, coffee cakes, and fruit compotes are typical brunch fare. Alcoholic drinks such as Bloody Marys (vodka with spiced tomato juice), Mimosas (champagne with orange juice), or screwdrivers (vodka with orange juice) might also be served.

### The Best Way to Start the Day

No matter what is on the menu, research shows that breakfast is still a very important meal. In a 1998 study of schoolchildren published in the *Archives of Pediatric and Adolescent Medicine*, researchers found that children who eat breakfast perform better academically and also behave better. The children who ate breakfast functioned intellectually at almost a grade level higher than those who did not, and were less likely to fall asleep at their desks or disrupt class because of hunger. The same goes for

adults. Eating breakfast improves the ability to concentrate, reduces the risk of heart disease, improves weight control, and increases strength and energy. Generally, health professionals recommend that we eat a healthy breakfast consisting of protein, whole grains, and fruits that totals about one-third of our daily caloric intake (Maynard).

Judith M. Fertig

**BRILLAT-SAVARIN, JEAN ANTHELME.** The author of the best-known work of gastronomy, Jean Anthelme Brillat-Savarin (1755–1826), was born in Belley in the region of Bresse, studied law in Dijon, became a lawyer and president of the civil court at Ain, a mayor of Belley, and a commander of the National Guard. In 1789 he was chosen to be a deputy to the National Assembly. In 1793 the Revolutionary Tribunal accused him of "moderatism" and he fled to Switzerland, Holland, and finally America. In New York he supported himself for

three years by teaching French and playing the violin in the John Street Theatre, but he also traveled north through New England, where he hunted game in good company, and south to Philadelphia where he met Thomas Jefferson. Returned to France in 1796, he was appointed judge to the Supreme Court of Appeals in Paris.

As a bachelor gourmand, he entertained often in his home on the Rue de Richelieu and frequented such stylish restaurants as Grand Véfour and Beauvilliers. Known to be a learned and witty man, he wrote treatises on a number of different sciences and wished to make a science of culinary art.

In 1826, he published anonymously the *Physiologie du goût: Méditations de gastronomie transcendante, ouvrage théorique, historique et à l'ordre du jour, dédié aux gastronomes parisiens* (*Physiology of Taste, or Meditations on Transcendental Gastronomy: a theoretical, historical and contemporary work, dedicated to the gastronomes of Paris*), a collection of aphorisms, epigrams, anecdotes, and essays on subjects as diverse as chemistry, physiology, nutrition, obesity, appetite, gourmandism, digestion, dreams, frying, and death. He even included a miniphilosophic history of cuisine from man's discovery of fire to the tables of Louis XVI.

## THE PHYSIOLOGY OF TASTE

"Tell me what you eat, and I shall tell you what you are" (Fisher, p. 3).

"The discovery of a new dish does more for human happiness than the discovery of a star" (p. 4).

"A dinner which ends without cheese is like a beautiful woman with only one eye" (p. 4)

"Let one open any book of history, from Herodotus to our own days, and he will see that, without even excepting conspiracies, not a single great event has occurred which has not been conceived, prepared, and carried out at a feast" (p. 54).

"Whosoever pronounces the word 'truffle' gives voice to one which awakens erotic and gastronomical dreams equally in the sex that wears skirts and the one that sprouts a beard" (p. 93).

Although his aim was didactic, his gift was for storytelling—his anecdotes rather than his analyses make his work live. His timing and his tone were right for the new bourgeoisie of Paris and the form of his *Physiology* helped establish the popularity of a new essayistic genre, the profile. Translated into many languages, his work has enjoyed a wide readership because of his light and easy style, his facility with a phrase—so quotable that his aphorisms have become clichés—and finally his intellectual solidity in placing the physical and aesthetic pleasures of food in the social-scientific context of human behavior.

In short, he took the subject of food seriously in a new way. Instead of elaborating an aesthetics of taste, based on the idiosyncrasies of individuals in the manner of his aristocratic contemporary Grimod de la Reynière, Brillat-Savarin attempted to find general principles that would liberate taste from autocratic authorities. His attempt to provide a scientific basis for all the pleasures of the table was compatible with the reasoned conservatism of the Enlightenment that had earlier sent him into exile. His *Physiology* is a remarkably egalitarian work.

At the same time, he epitomizes the urbane civility of a man born in the country who rose to high office in the city in the new ranks of the Parisian bourgeoisie. Others, striving to improve their social standing, could identify with him. As Brillat-Savarin outlined them, his standards of excellence were no longer defined by professional chefs of the court or by grand banquets of court cuisine, but by the quality of ingredients and a care of preparation that anyone could learn. He rhapsodizes over cheese, eels, or truffles not because they are extravagant luxuries but because they are part of a well-stocked larder that any man of means could buy and serve at home. For

the convenience of his readers, he took care to include the names and addresses of his favorite Parisian suppliers of groceries, pastries, and breads. In effect, although a habitué of the best restaurants in town, he was essentially addressing the home cook and the home diner.

Although writing almost two centuries ago, he describes a culinary world that seems familiar to any inhabitant of a large cosmopolitan city in the early twenty-first century. In praising the Parisian table, he does not ascribe its virtues to an indigenous French character, but rather to the fruits of an increasing internationalism. He lists which ingredients come from France, which from England, Germany, Spain, Italy, Russia, Africa, Holland, and America. He concludes: "a meal such as one can eat in Paris is a cosmopolitan whole in which every part of the world makes its appearance by way of its products" (Revel, *Culture and Cuisine*, p. 218). He fancied himself a citizen of the world and as a result his name has become synonymous, at least in the Western world, with food's most civilized expression of wit and humanity.

### ENGLAND

Since the 1970s, English food appears to have undergone a transformation. A postwar cuisine of plainly cooked meat and vegetables supplemented with baked goods and puddings has apparently given way to multiculturalism. Restaurants serve fusion food. Supermarkets sell chilled meals based on Italian or Asian recipes. The cookery sector of publishing is buoyant. This seems astonishing for a country whose eating habits evolved little between the

The interior of Covent Garden in London, circa 1920. This market hall was one of the largest in England as well as the center of London's food distribution system until after World War II, when it was closed due to traffic congestion. ROUGHWOOD COLLECTION.

mid-nineteenth century and 1953, when Second World War rationing ended; but beneath the metropolitan froth, old ideas about plain cooking live on.

### Background

England has an unpredictable but generally benign maritime climate, without extremes; relief is low, the highest mountain standing 3210 feet (978 meters). A basic topographic division runs from northeast to southwest, along the watershed of the Trent and Severn rivers. North and west of this, the land tends to be higher, and the climate colder and wetter. To the south and east, hills are generally low, and summers warmer and drier. Annual rainfall ranges from about 97 inches (2,500mm) in the hills of the northwest to about 23 inches (600mm) in the driest parts of the east; winter temperatures rarely drop more than a couple of degrees centigrade below freezing and the summer maximum is about 86°F (30°C).

England's political and cultural dominance of the United Kingdom makes it difficult to disentangle Eng-

lish food habits from those of the Welsh, Scots, and Irish. Successive waves of settlers have brought ideas about food, but few attributions can be made until the twentieth century. Foreign trade has been important to English cuisine since at least the late Middle Ages. Spices came from the East Indies; sugar and currants were initially imported from the Mediterranean, and later from colonial possessions. A dependence on tropical crops—tea, coffee, chocolate, sugar—developed in the nineteenth century; and the idea of curry came home with the nabobs of the East India Company.

### Meat

Localized breeds of cattle, sheep, and pigs developed in the nineteenth century. Grass-fed beef from Aberdeen Angus, Hereford, and other traditional breeds is considered best. Most sheep meat is eaten as lamb, under the age of a year; mutton, from older sheep, formerly important, is now almost unobtainable. Fresh pork was and is popular, as is bacon. Wiltshire became an important

center for curing meat in the nineteenth century. Bacon provided a relish for the otherwise monotonous diets of the poor. It remains an English favorite, though much is now imported from Denmark. Regional ham cures that became famous include those of York (or, more properly, Yorkshire), Cumberland, Devon, and Suffolk.

Poultry has long been important for both meat and eggs. In the nineteenth century, the counties around London produced Sussex and Dorking chickens; Surrey was famous for capons, and the town of Aylesbury produced ducks. Turkeys and geese were reared on corn (grain) stubble in East Anglia for sale in the capital. Poultry production is now an intensive industry, though small businesses based on high-quality traditional poultry production are appearing. Only geese have not succumbed to intensive systems.

Game has always featured on the aristocratic menu. Venison was most sought after; deer farming has made this more accessible, but it remains a minority taste, as do hares. Rabbits, nurtured in warrens in the Middle Ages, escaped, naturalized, and became pests, and the only wild creatures easily accessible to the poor. Wildfowl of all descriptions were eaten up to the eighteenth century, but subsequently the choice narrowed to about a dozen species, of which pheasants are most common, yet grouse from heather moorlands, and partridges are most prized.

### Meat Cookery

Meat cookery demonstrates a preference for plain roasted (or, strictly speaking, baked) meat. Traditional accompaniments are horseradish sauce for beef; mint sauce (finely chopped mint mixed with sugar and vinegar) for lamb, and sage and onion stuffing and applesauce for fresh pork, which is generally roasted with the skin on to make crackling. Roast potatoes and boiled green or root vegetables are also served. Boiled meat dishes, such as salt beef with carrots, or mutton with caper sauce have almost vanished, though some people still marinate beef with salt, spices, and sugar for several days to make spiced beef. Steaks and chops are used for grilling.

Other meat dishes include pies or steamed suet puddings of beefsteak and kidney; oxtail is made into stews and soups. Skirt of beef is mixed with chopped potato, onion, and turnip in Cornish pasties, popular everywhere but closely identified with Cornwall itself. Northern butchers make a paste of cooked beef beneath a layer of fat; this potted beef is a remnant of an eighteenth-century tradition of potting all kinds of meat. Lancashire hotpot is a traditional stew of lamb or mutton chops with layers of onions and potatoes. It evolved in an area where a high rate of female employment led to a reliance on slow-cooked and ready-prepared foods.

Pork products include fresh sausages of lean and fat meat and some type of grain; the Cumberland type, with a high meat content and distinctive coiled presentation, is considered particularly good. Pork pies, survivors of a

## PUDDINGS

Pudding has two different but linked meanings. It can indicate any sweet food considered suitable for dessert, ranging from fresh fruit to the most elaborate of sweet dishes. This usage developed after puddings, a fairly neutral staple food in the seventeenth century, evolved a subset of heavily sweetened dishes eaten for the second course at dinner.

Older meanings relate pudding to specific groups of dishes, some savory, some sweet. The oldest group is represented by sausage-type products such as black puddings (blood, fat, and grain) and white puddings, well documented since the sixteenth century. Bag puddings, mixtures of suet and flour or breadcrumbs, wrapped in a cloth and boiled, were known by the seventeenth century, and developed two distinct types. One was the sweet suet pudding with lemon peel, currants, sugar, and spice. Plum pudding, a heavily enriched version with raisins, candied peel, and sugar, has become a symbol of Christmas and remains essentially unchanged since the eighteenth century. Other sweet puddings include versions filled with fresh seasonal fruit, or jam roly-poly, suet crust spread with jam and rolled up, which became a school dinner staple. The second type was the savory suet pudding with a meat filling. These were recorded by the nineteenth century: steak and kidney remains a favorite, though puddings made with steak and oysters, mutton, and game such as partridges are also recorded.

Other ancient pudding types are pease pudding, based on a puree of dried peas, eaten with boiled bacon or ham, and Yorkshire pudding, made from batter baked in a popover pan, the principal survivor of numerous recipes for batter puddings boiled or baked.

In the eighteenth century, many sweet puddings using pastry and fruit or nuts became fashionable. Mixtures of rice or sago with milk and sugar also became common. These remain popular, though often in debased "nursery" versions. Puddings, steamed or baked, based on sponge-cake mixtures, flavored with lemon, ginger, or cocoa, became popular in the mid-nineteenth century, as did summer pudding, based on bread and fresh summer fruit.

great tradition of raised pies, are made with a lard-based hot-water crust. Melton Mowbray in the Midlands is famous for a fine version. Black puddings (blood sausages), highly seasoned mixtures of blood, grain, and cubes of fat, are known everywhere but have a strong association with the industrial towns of south Lancashire (as does ox

Salted kippers from Cumbria, England, are one of the traditional breakfast specialties of the country, but they are an acquired taste for outsiders. They are salted prior to smoking, hence the distinctive flavor. © JACQUI HURST/CORBIS.

tripe). Hog's puddings, of seasoned grain and fat, are popular in the southwest. Other items include faggots, chopped offal wrapped in squares of caul; haslet, a kind of loaf made from scraps of lean and cured pork; and brawn, a cold jellied dish made from meat picked from the head. Lard, beef suet, and drippings are important in traditional cookery.

Chicken, once an expensive treat roasted for special occasions, is now ubiquitous. It is much used in dishes of foreign origin. Rabbit stews and pies became poverty food, and the taste for them has waned. Hare soup and jugged hare—cooked slowly with wine and herbs, the sauce thickened with the blood of the animal—are classic dishes of English game cookery.

## Fish

Cod and haddock, though becoming scarce, are staples of fish and chip shops; grilled Dover sole is a standard of English restaurant cookery. Oysters, until the mid-nine-

teenth century a cheap food, suffered from pollution and disease and are now a luxury. Morecombe Bay shrimps (*Crangon crangon*), potted in spiced butter, are a traditional teatime delicacy. Eels, until the 1970s, were closely associated with the food habits of the London poor. Eel pie, and mash (mashed potatoes) shops sold them cold as jellied eels (boiled and allowed to cool in their liquid) or hot with mashed potato and "liquor," a green parsley sauce. Herrings were important until a recent decline in fish stocks. Some were eaten fresh, but most were preserved. Red herrings (heavily salted and smoked for long-term keeping) were superseded in the nineteenth century by lighter cures: kippers (split and cleaned before smoking) evolved in Northumberland, while Yarmouth favored bloaters (whole, lightly salted smoked herrings). Salmon, which became expensive when rivers were polluted during the nineteenth century, is cheap again because of fish farming, and poached salmon with cucumber is an English summer favorite.

## Bread and Baking

White wheaten (wheat) bread is of primary importance. Traditional oblong tin loaves have become degraded under industrial production, and foreign influence makes it easier to buy croissants, ciabatta (a bread of Italian origin with a chewy, open texture), pita, or nan bread than a traditional cottage loaf (two-tiered round loaf). Historically, bread grains included rye, barley, and maslin (mixed grain). In the northern hills, oats, the only reliable grain crop, were used for flatbreads. By the seventeenth century a preference for wheat had developed in the London area. Variety diminished as the taste for wheat spread and grain imports grew in the nineteenth century. Now, only the oat-bread tradition survives. Haverbread (from Old Norse *hafre*, oats), flat ovals about a foot long, can occasionally be found in towns on the Yorkshire-Lancashire border. A stronger custom of baking floppy oatcakes about ten inches in diameter continues in Staffordshire. Barley is now grown for brewing.

There are many small regional breads. Kentish huffkins, Cornish splits, and Yorkshire teacakes are all round and flattish, enriched with a little sugar, lard, and dried fruit. Hot plates are used to bake muffins (made from soft bread dough), and also crumpets, and pikelets (both made from thick, yeast-leavened batter). This trio of foods are all eaten toasted and spread with butter for breakfast or tea. Scones, of flour, sugar, egg, and dried fruit, are common. Chelsea buns and Bath buns are rich and sweet. Hot cross buns, marked with a cross on top, are plainer and spiced; formerly made only on Good Friday, they are now produced for several weeks around Easter.

Lardy cakes made from bread dough folded with lard, sugar, and dried fruit are typical of southern England. Currants, raisins, and candied peel feature in yeast-leavened Guernsey gâches, Cornish saffron cakes, and Yule loaves (sweetened Christmas breads made in the north). Rich fruit cakes are related to these breads his-

torically. Modern versions are heavy with sugar, butter, raisins, currants, and candied cherries. Covered with almond paste and sugar icing, they are essential for Christmas or weddings; baked with a marzipan layer in the middle, they become simnels, for Easter.

The taste for dried fruit extends to Eccles, Chorley, and Banbury cakes—spiced currant mixtures wrapped in puff pastry. Small mince pies, filled with a mixture of dried fruit, spices, and sugar, are eaten all over the country throughout the Christmas season. Originally the mincemeat filling did contain veal, mutton, or beef; now, an enrichment of beef suet is all that survives of this. Such dried fruit and pastry confections have been popular for at least four hundred years.

Ginger is popular in baking. Grasmere gingerbread comes from the Lake District, where local ports were active in the West India trade and a taste for brown sugar, rum, and ginger survives. Parkin is a north-country gingerbread that often contains oatmeal. Cornish Fairings and Ashbourne cakes are also ginger-flavored, and have a crisp, biscuity texture. The diversity of modern British biscuits (cookies) is a product of nineteenth-century industry, but Shrewsbury cakes (related to shortbread) were recorded in the seventeenth century, and Bath Olivers (plain biscuits) in the early nineteenth.

### Vegetables and Fruit

The English have never been renowned for sensitivity in cooking vegetables, which were generally boiled and served with butter. Cabbages, carrots, parsnips, spinach, and salads such as lettuce and watercress have a long history of use, as has asparagus: the Vale of Evesham and Norfolk are particularly associated with this crop. One

The center of English social life is the village pub, where all manner of truths and confessions are part of the daily fare. Oftentimes the food is minimal, but at the best establishments it vies with high-class home cookery, as in the case of this famous pub in Boston, England. © JAMES L. AMOS/CORBIS.

### FISH AND CHIPS

Fish and chips, a favorite take-away (takeout) food in England, are sold in their own specialized restaurants and shops. There is some debate about when the combination became popular, but fried fish was being sold as street food in London as early as the 1830s, when Charles Dickens mentioned a fried-fish warehouse in *Oliver Twist*. Chips (french fries) appear to have joined the fish by the 1880s, and the pairing has remained popular ever since.

Cod is most commonly used, though haddock is preferred in some areas; the fillets are dipped in batter before deep-frying. For chips, the potatoes are cut in thick fingers and deep-fried. Vegetable oil is the usual frying medium in the south. Beef drippings are often used in the north. On purchase, the cooked fish and chips are seasoned with salt and vinegar as the customer desires. A pot of mushy peas (cooked marrowfat peas) is sometimes added to the order. Traditionally, newspapers are used for wrapping fish and chips, and the smell of deep-frying combined with hot newsprint is part of the experience. Health regulations now demand layers of greaseproof paper to insulate the food from printer's ink.

vegetable almost uniquely used by the English is sea kale (*Crambe maritima*); wild plants were overexploited in the nineteenth century but sea kale is now cultivated in small quantities. Potatoes first gained wide acceptance in the north; by the nineteenth century they were eaten everywhere by everyone, and have continued to be so.

Apples, pears, cherries, and plums are traditional fruit crops of the southeast and southwest. Cobnuts are grown in Kent; soft fruit is grown across much of the country, strawberries and raspberries being favorites. Historically, the north, with a more challenging climate, relied on gooseberries, damsons, and rhubarb, the latter mostly grown in West Yorkshire, where it is forced as an early spring crop. Traditional fruit puddings and jams are a strength of the English kitchen. One vital item, the bitter orange, is grown in southern Spain and imported specifically for making breakfast marmalade. A taste for sugar confectionery has led to numerous boiled sugar sweets, many using fruit flavorings.

### Dairy Products

Dairy products were considered food for the poor in the seventeenth century, but have become progressively more important. Cream is mixed with fruit purees for fools, and beaten with wine and lemon for syllabubs. Clotted cream,

## MUFFINS AND MUFFIN-MEN

As late as the 1930s, muffins were sold in London by muffin-men, street vendors who announced their presence by ringing a bell. In 1851, Sir Henry Mayhew recorded in *London Labour and the London Poor* that muffin-men bought their wares fresh from the bakers. The muffins were kept warm by wrapping them in flannel; they were then carried through the streets in baskets for resale door-to-door. The custom apparently derives in part from genteel ladies who did not keep servants who could be sent on errands, but who liked a slap-up (lavish) tea. The muffin-men recognized this, and made their rounds in mid-afternoon, convenient for tea time. Muffins were most popular in winter. To eat them, they were toasted, pulled apart around the circumference, spread with butter, and the halves put back together to allow the butter to melt.

The origin of the name is a mystery. Recipes appear in the mid-eighteenth century, but the idea is probably much older. Muffins enjoyed great popularity but were considered old-fashioned by the early twentieth century, and had almost vanished by the Second World War. In the 1980s, they were revived by industrial bakeries, and are once again available, in varying degrees of quality. Muffins in England—quite unlike sweetened muffins and what people in North America call “English muffins”—are disks about four inches in diameter and an inch thick, and made from plain, soft bread dough. Size and the use of yeast as a leaven relates them to the many other small breads of English traditional baking, while the use of a hot plate puts them in the same category as crumpets, pikelets, and several Welsh and Scottish specialties.

heated gently to produce a thick crust, is a specialty of Devon and Cornwall. Butter is essential for spreading on bread and toast, as well as in cooking generally. Cheese-making in Britain was centralized during the Second World War, concentrating on “territorial” cheeses—Stilton, Cheddar, Gloucester, Cheshire, Lancashire, Wensleydale, Derby, and Leicester. All named for their areas of origin, they became generic (apart from Stilton, the manufacture of which was restricted to a small area in 1910). A dwindling nucleus of farm cheese-makers was boosted in the 1980s as “new wave” artisans who injected new creativity and energy into the industry.

### Meal Times and Names

The British all recognize the early morning meal as breakfast, but after that a division becomes apparent. One

pattern is a light midday lunch, perhaps afternoon tea, and a large dinner in the evening. The other is midday dinner and a substantial tea in the early evening. Sometimes this is called high tea or supper, though “supper,” confusingly, is also used to indicate a light, late-evening repast. This divide originated when dinner, once a midday meal, slipped first to the early evening and then as late as 8:00 P.M. in the early nineteenth century. Lunch and afternoon tea developed to fill the long hours between breakfast and dinner. Wealthy younger people and southeasterners tend toward the lunch and dinner pattern. Poorer people, older ones, and northerners follow, to a diminishing extent, the dinner and tea pattern.

**The “full English” breakfast.** There is much nostalgia for the full English breakfast, a meal now mostly encountered in hotels, guesthouses, and cafés. Fried bacon and eggs are essential. Tomatoes, mushrooms, baked beans, fried bread, sausages, and black pudding are often added. Toast and marmalade generally follow. In cafés this meal is often available at any time. Time-consuming to prepare and eat, it is rarely made at home on a workday, when breakfast usually consists of cereal or toast, or coffee and a pastry bought on the way to work. However, cooked breakfasts are often made as a weekend treat.

Other items sometimes found at breakfast are oatmeal porridge (now closely identified with Scotland, but a survivor of a general British tradition of grain pottages) and kippers. In India, the British took *khichri*, spiced rice and lentils eaten with dried fish, and transmuted it into kedgeree, a mixture of rice, onions, and smoked haddock, still popular. Substantial breakfasts were most fully developed in country houses in the mid-nineteenth century, when huge buffets including such delicacies as deviled kidneys, raised pies, and cold tongue were laid out.

**Lunch.** Lunch has few special foods linked with it; though large formal lunches are sometimes eaten, a collation of odds and ends is more frequent. Sandwiches are a popular choice. The English have found sandwiches a convenient handheld meal since the mid-eighteenth century, when the Earl of Sandwich is said to have asked for his meat between two slices of bread, so as to avoid leaving the gaming table. Currently enjoying a zenith of popularity and variety, numerous specialty shops sell them filled with anything from conventional cheese and pickles or roast beef and horseradish combinations to chicken *tikka* or prawns and avocado. For those who want a hot lunch, soup or “something on toast”—cheese, eggs, fish, baked beans—are popular.

**Dinner.** Dinner is a substantial hot meal, whether taken at midday or in the evening. The traditional pattern is cooked meat or fish with vegetables. A sweet course, usually referred to as pudding, follows. Food may come from the prepared-food counter in a supermarket, and home cooks are as likely to choose dishes from the Mediterranean or the Indian subcontinent as traditional English ones. Take-away (takeout) food, from traditional fish and

English country fare has undergone a revolution, in part due to high-end tourism and to a process of rediscovery among English food enthusiasts who want to see more of the country's culinary treasures showcased to visitors. Here, traditional English veal shin is baked in a clay pot with various root vegetables at Le Manoir, Great Milton, Oxfordshire, England. © MICHAEL BOYS/CORBIS.

chips to kebabs, curries, or “a Chinese,” are possible choices.

Confounding the lunch-dinner division are the special cases of Sunday dinner and Christmas dinner. These phrases still imply a large midday meal. Sunday dinner is often roast beef and Yorkshire pudding, served with gravy made from the meat juices or a commercial mix. Roasted or boiled potatoes and other vegetables, typically boiled cabbage and carrots, are also served. Lamb, pork, or chicken may take the place of the beef. Pudding choices include trifle (sherry-soaked sponge cake covered with layers of custard and cream); treacle tart (filled with golden syrup, lemon, and breadcrumbs), or lemon meringue pie. Steamed suet or sponge puddings are seen as old-fashioned but remain popular, as do fruit pies.

Christmas dinner usually centers on turkey or goose accompanied by sage and onion stuffing. Bread sauce, milk infused with cloves and shallot, thickened with breadcrumbs, is a classic accompaniment and a survival of a medieval tradition of bread-thickened sauces. Brussels sprouts are generally among the vegetables. This is followed by Christmas pudding flambéed with brandy, served with rum or brandy butter. Turkey is now the general choice, a reflection of centuries of great feasts involving various bird species, though roast beef was also a standard Christmas dish until the nineteenth century.

**Afternoon tea and high tea.** Tea is overlaid with social nuances. Apart from tea to drink (a beverage of primary

importance in England since the mid-eighteenth century), afternoon tea is a dainty meal: bread and butter, small sandwiches filled with cucumber, a cake. Cream tea is a variant on this, with scones, jam, and cream. Elaborate afternoon teas are now most often taken in a café. High tea is a substantial meal, for people returning from work, or for children after school. It involves hot food such as kippers, eggs, pies, or sausages, or, in summer, cold ham or tinned canned salmon and salad. Bread and butter is always on the table, together with jam, and a selection of cakes—large ones, such as fruit cake or a Victoria sandwich (sponge cake filled with jam and cream), and small fairy cakes (similar to cupcakes or miniature muffins), jam tarts, and cookies.

### Recent Developments

A trend toward vegetarianism and concern about animal welfare has become apparent since the 1970s, leading to a growth in consumption of organically produced and vegetarian foods. Another development is a taste for ethnic food. Though imitations of Asian food, such as curry, piccalilli, and mushroom ketchup, have been made since the eighteenth century, in the last hundred years immigrant communities have introduced numerous new ideas. Chinese restaurants were widespread by the 1960s and Italian restaurants soon followed. Indian restaurants began to penetrate beyond major centers of immigration in the 1970s, putting dishes such as chicken *tikka masala* on the national menu, especially after pub closing time. West

Indian, Hispanic, Turkish, and Thai restaurants can now be found in most cities.

London restaurant culture now has a global reputation for excellence, and interest in eating healthily has increased; but London is not England, and the high incidence of cardiovascular disease throughout the country is partially attributed to poor diet. Writers, guides, and chefs have raised the variety and quality of ingredients and of ready-prepared food, and cookery is a popular subject for television. But the best traditional English food remains a specialty found mostly in the homes of dedicated cooks.

## IRELAND

The first settlers, the Mesolithic people, came to Ireland about 7000 B.C.E. and lived by hunting, fishing, and gathering. Neolithic colonists introduced domestic animals and crops about 4000 B.C.E. Cultivated cereals included emmer wheat (*Triticum dicoccum*), bread wheat (*Triticum aestivum*), and barley. Wild foods, such as hazelnuts and dried crabapples, were stored. Farming, crops and livestock, continued during the Bronze Age (2000–700 B.C.E.) and the pre-Christian Iron Age (700 B.C.E.–500 C.E.), as is evident from faunal remains and from the range of quernstones for saddle, beehive, and disk querns used to process cereals for domestic use.

In the historical period literary data of various kinds supplement the archaeological record. Religious texts in Old Irish and Latin from the Early Christian period (500–1000 C.E.) describe monastic and penitential diets, and the Old Irish law tracts of the seventh and eighth centuries provide insight into food-production strategies, diets, and hospitality obligations. Prestige foods are correlated with social rank according to the general principle that everyone is to be fed according to his or her rank. Persons of higher social status enjoyed a greater variety and quality of food than those of lower rank. Milk and cereal products were the basis of the diet, and a distinction was sometimes made between winter and summer foods. The former apparently consisted of cereals and meat and the latter mainly of dairy produce.

### Milk and Milk Products

Milk, “good when fresh, good when old, good when thick, good when thin,” was considered the best food. Fresh milk was a high-status food of sufficient prestige to be served as a refreshment to guests in secular and monastic settings. Many milk products are mentioned in the early Irish legal tracts and in *Aislinge Meic Con Glinne* (Vision of Mac Con Glinne), an early medieval satirical text in the Irish language rich in food imagery and probably the most important source of information about food in medieval Ireland. Butter, curds, cheese, and whole-milk or skim-milk whey were common elements of the diet. Butter was often portrayed as a luxury food. It was part of the food rents a client was obliged to give to his or her lord and a festive food for monastic communities. Curds, formed naturally in milk or by using rennet, were a common summer food included in food rents and apparently a normal part of the monastic diet. Cheese, in soft and hard varieties, was of great importance in the early Irish and medieval diet. Whey, the liquid product of the preparation of curds and cheese, was rather sour, but diluted with water it was prominent in the stricter monastic diets of the early Irish Church. Goat's milk whey, considered to have medicinal properties, was still in regular use in parts of Ireland in the early nineteenth century.

These milk products held their ancient status in the diet to varying degrees until the threshold of the eigh-

teenth century, when forces of commercialization and modernization during the modern period altered levels of consumption and ultimately the dietary status of some milk products. Milk and butter remained basic foodstuffs, and their dietary and economic significance is reflected in the richness of the repertoire of beliefs, customs, and legends concerned with the protection of cows at the boundary festival of May, traditionally regarded as the commencement of summer and the milking seasons in Ireland, when the milch cows were transferred to the lush green pastures. Cheese making, which essentially died out in the eighteenth century, probably due to the substantial international butter and provisions trade from Ireland, made a significant comeback in the late twentieth century.

### Cereal Products

Wheat products were consumed mainly as porridge and bread in early and medieval Ireland. Porridge was food for children especially, and a watery type figured prominently as penitential fare in monasteries. Wheaten bread was a high-status food. Climatic conditions favored barley and oat growing. Barley, used in ale production, was also a bread grain with monastic and penitential connotations. Oat, a low-status grain, was probably the chief cereal crop, most commonly used for oaten porridge and bread. Baking equipment mentioned in the early literature, iron griddles and bake stones, indicates flat bread production on an ovenless hearth. Thin, unleavened oaten bread, eaten mostly with butter, was universal in medieval Ireland and remained the everyday bread in parts of the north and west until the nineteenth century. Barley and rye breads or breads of mixed cereals were still eaten in parts of eastern Ireland in the early nineteenth century.

Leavened wheaten bread baked in built-up ovens also has been eaten since medieval times, especially in strong Anglo-Norman areas in East Ireland, where commercial bakeries were established. English-style breads were available in cities in the early seventeenth century, and public or common bake houses are attested from this period in some urban areas. Built-up ovens might be found in larger inns and prosperous households, but general home production of leavened bread, baked in a pot oven on the open hearth, dates from the nineteenth century, when bicarbonate of soda, combined with sour milk or buttermilk, was used as a leaven.

A refreshing drink called sowens was made from slightly fermented wheat husks. Used as a substitute for fresh milk in tea or for sour milk in bread making when milk was scarce, it replaced milk on Spy Wednesday (the Wednesday of Holy Week) and Good Friday as a form of penance. A jelly called flummery, procured from the liquid by boiling, was widely used.

### Meat, Fowl, and Fish

Beef and mutton have been eaten in Ireland from prehistoric times, and meat was still considered a status food

Wrought iron oatcake drier or hardening stand, Ireland, nineteenth century. Thin, unleavened oatcakes were baked on a griddle then placed upright on the stand to dry before the open fire. COURTESY OF THE DEPARTMENT OF IRISH FOLKLORE, UNIVERSITY COLLEGE, DUBLIN.

in the early twenty-first century. Pigs have been raised exclusively for their meat, and a variety of pork products have always been highly valued foodstuffs. Domestic fowl have been a significant part of the diet since early times, and eggs have also figured prominently. Wild fowl have been hunted, and seafowl provide seasonal, supplementary variations in diet in some seacoast areas.

Fish, including shellfish, have been a food of coastal communities since prehistoric times. Freshwater fish are mentioned prominently in early sources and in travelers' accounts throughout the medieval period. Fish were included in festive menus in the nineteenth century and were eaten fresh or cured in many ordinary households while the obligation of Friday abstinence from flesh meat remained in force.

### Beverages

Milk and whey were the most popular drinks in early and medieval Ireland, but ale was a drink of great social importance. It was also regarded as a nutritional drink suitable for invalids and was featured in monastic diets at the celebration of Easter. Mead made by fermenting honey with water apparently was more prestigious than beer. Wine, an expensive import, was a festive drink in secular and monastic contexts. Whiskey distillation was known from the thirteenth century. Domestic ale and cider brewing declined drastically after the eighteenth century in the face of commercial breweries and distilleries.

Nonalcoholic beverages, such as coffee, chocolate, and tea, were consumed initially by the upper sections of society, as the elegant silverware of the eighteenth and nineteenth century shows. But tea was consumed by all sections of society by the end of the nineteenth century.

### Vegetables and Fruit

From early times the Irish cultivated a variety of plants for food. Garden peas and broad beans are mentioned in an eighth-century law text, and it appears that some member of the allium family (possibly onion), leeks, cabbages, chives, and some root vegetables were also grown. Pulses were significant in areas of strong Anglo-Norman settlement in medieval times but were disappearing as a field crop by 1800, when vegetable growing declined due to market forces. Cabbage remained the main vegetable of the poor. Apples and plums were cultivated in early Ireland, and orchards were especially prominent in English-settled areas. Exotic fruits were grown in the walled gardens of the gentry or were imported for the large urban markets. A range of wild vegetables and fruits, especially crabapples, bilberries, and blackberries, were exploited seasonally.

### Edible Seaweeds

Edible algae have been traditionally used as supplementary food products along the coast of Ireland. Duileasc (*Palmaria palmata*), anglicized as “dulse” or “dilisk” and frequently mentioned in the early Irish law texts, is one of the most popularly consumed seaweeds in Ireland. Rich in potassium and magnesium, it is eaten raw on its own or in salads, or it is stewed and served as a relish or a condiment for potatoes or bread. Sleabhach (*Porphyra*), anglicized as “sloke,” is boiled, dressed with butter, and seasoned and eaten as an independent dish or with potatoes. Carraigín (*Chondrus crispus*), or carrageen moss, has traditionally been valued for its medicinal and nutritional qualities. Used earlier as a milk thickener and boiled in milk to make a blancmange, it has come to be regarded as a health food.

Collecting shore foods, such as edible seaweeds and shellfish, was a common activity along the Atlantic Coast of Ireland on Good Friday, a day of strict abstinence. The foodstuffs collected were eaten as the main meal rather than as an accompaniment to potatoes.

### Potatoes

Introduced in Ireland toward the end of the sixteenth century, the potato was widely consumed by all social classes, with varying degrees of emphasis, by the nineteenth century. Its widespread diffusion is evident in the broad context of the evolution in the Irish diet from the seventeenth century. In the wake of the English conquest of Ireland, the seventeenth and eighteenth centuries were a time of sustained transition in Irish economic, demographic, and social life. Demographic expansion beginning in 1600 led to a population in excess of 8 million by 1800. The food supply altered strikingly during that pe-

riod. The diet of the affluent remained rich and varied, while commercialization gradually removed milk and butter from the diet of the poor and resulted in an increased emphasis on grain products. The commercialization of grain and the difficulty in accessing land during the eighteenth century forced the poorer sections of society to depend on the potato, which was the dietary staple par excellence of about 3 million Irish people by the early nineteenth century. Fungus-induced potato crop failures from 1845 to 1848 caused the great Irish famine, a major human disaster.

Diets changed gradually in the postfamine years, and while the potato was but one of many staples by the end of the nineteenth century, it never lost its appeal. The ripening of the new potato crop in the autumn remained a matter for celebration. In many parts of the country the first meal of this crop consisted of mashed potatoes with scallions and seasoning. Colcannon, typically associated with Halloween, is made of mashed potatoes mixed with a little fresh milk, chopped kale or green cabbage, fresh onions, and seasoning with a large knob of butter placed on the top. In some parts people originally ate it from a communal dish.

Boiled potatoes are also the basic ingredient for potato cakes. The mashed potatoes are mixed with melted butter, seasoning, and sufficient flour to bind the dough. Cut into triangles, called farls, or individual small, round cakes, they are cooked on both sides on a hot, lightly floured griddle or in a hot pan with melted butter or bacon fat. Apple potato cake or “fadge” was popularly associated with Halloween in northeast Ireland. The potato cake mixture was divided in two, and layers of raw sliced apples were placed on the base, then the apples were covered with the remaining dough. The cake was baked in the pot oven until almost ready. At that point the upper crust was peeled back, and brown sugar was sprinkled on the apples. The cake was returned to the oven until the sugar melted. “Stampy” cakes or pancakes were raw grated potatoes sieved and mixed with flour, baking powder, seasoning, a beaten egg, and fresh milk and cooked on the griddle or pan.

The menus of restaurants that offer “traditional Irish cuisine” include such popular foods, which also were commercially produced by the late twentieth century. But as Irish society becomes increasingly pluralistic, the so-called “international cuisine” and a wide range of ethnic restaurants characterize the public provision of food in major urban areas. In the private sphere, however, relatively plain, freshly cooked food for each meal is the norm. Milk, bread, butter, meat, vegetables, and potatoes, though the last are of declining importance, remain the basic elements of the Irish diet.

## SCOTLAND

In Scotland food and food traditions have, as elsewhere, changed over time while regional influences have had a major effect. In addition, both Europe and Scandinavia have introduced changes in the food of the country. Geography has played a central role in determining the basic foodstuffs and their place in the diet. The country is divided into two areas, the Highlands in the north and west, and the Lowlands in the south and east. Each has its own distinct language and culture. The Highlands are generally a mountainous region, with an emphasis on pastoral activities, livestock husbandry, crofting (small acreage farming), general agriculture, and maritime activities. The Lowlands are the chief agricultural area.

Beginning with the Agricultural Revolution of the late eighteenth and early nineteenth centuries, the area developed specialized agricultural districts. The east is predominantly an area of arable and crop production; the climate of the west makes it suitable for the raising of

Oat cake roller for breaking up oat cakes into coarse crumbs for use in puddings and porridge, circa 1800. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

livestock. The major towns and cities are located in this region, between the Firths of Forth and Clyde. These two areas are divided into smaller ones. The South-West, including the Inner Hebrides, is a dairying area; the East and South-East are advanced grain-cropping areas with a European reputation for farming; the North-East is a stock rearing area, especially for beef; the Highlands and Islands are another stock area.

A number of foods and foodstuffs have been important in the Scottish diet. Cereals have played a central role, especially in rural areas. Bere, a barley, was the traditional grain. By the end of the seventeenth century, it was being rapidly supplanted by oats. Beginning in the eighteenth century oats came to be recognized as a mark of Scottish nationality. As its consumption grew, bere fell down the social scale, though it continued to be eaten in Caithness and Orkney in the early twentieth century. Bere and oats were eaten in a number of ways. Oatmeal was milled into a number of "cuts" or grades, used for specific dishes. It was the basis of brose (mixed with water to make an instant food), porridge (cooked with water or milk), and such foods as sowens and skirley (mixed with fat and onion). Oatmeal was an ingredient in dishes such as haggis (mixed with liver and suet, traditionally cooked in a sheep's stomach). It was baked into bannocks and oatcakes, often toasted over an open fire.

Wheat was a grain grown in only the most favored areas and sold as a cash crop. Wheat bread was at first a prestigious food, eaten by the higher classes; for the lower classes it was eaten on special occasions such as harvesting. In the late eighteenth century, it spread from

Scottish shortbread stamp with swan motif circa 1870. These stamps, or “prints” as they were called, were carved by craftsmen who traveled from village to village selling them during the summer months. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

the towns and cities, where it was accompanied by the rise in baker’s shops. Peas and beans were bread crops. Especially in the Lowlands, they were made into meal, but also put into dishes such as broths. These grains also indicated social class, and by the seventeenth century they were confined to the poorer people.

### Baking

These grains, especially oats and wheat, were used in the tradition of baking, for which Scotland has become renowned. From oats, bannocks, scones, and oatcakes were baked. These did not use raising agents. From wheat, cakes, pastry, and shortbread were oven-baked. This was a later development, owing to the late introduction of the oven and the initial high cost of sugar.

### Potatoes

The potato was introduced as a novelty in the late seventeenth century. In the 1740s there was resistance against eating it. By the 1790s when the “Statistical Account of Scotland” was compiled, it had become an important element of the diet, especially in Highland areas and among the poorer classes of the Lowlands. It was a principal food in the diet and was a cheap and healthy food and a substitute for bread. The potato continued to be an important element and only declined in status in the 1990s in the face of increased use of pasta and rice. Traditionally potatoes were boiled, with or without their skins. In the urban diet of the late nineteenth century and throughout the twentieth century and beyond, they were sliced and deep-fat fried as chips. They were eaten as a

meal, as a side dish in a main meal, or as an ingredient in a wide range of dishes such as soups and stews; they were also used in baking, as in potato scones.

### Fruits and Vegetables

Fruit and vegetables had a relatively small role in the diet. The traditional staple vegetable was kale, a member of the *Brassica* varieties. Vegetable gardening around the houses of noblemen and lairds, and the rise of market gardening in the vicinity of the large towns, especially from the eighteenth century onwards, meant the development of a wide range of vegetables. Like other foodstuffs, they were at first eaten by the wealthy classes, then spread to the social classes below. Traditionally they were consumed as broth. Fruit was not extensively grown, and a limited number of varieties were raised. Orchard fruit was little cultivated, though soft fruit, especially strawberries and raspberries, has been commercially grown from the late eighteenth century; fruit was supplied from kitchen gardens. Especially where domestic production was limited or not undertaken, fruit growing wild in nature provided an important source. It could be a fruit substitute, as were rosehips during World War II. Fruit was eaten raw, or made into dishes, puddings, sauces, and drinks, including alcoholic ones. When sugar became available, it was made into preserves, jams, and jellies, or was bottled.

### Dairy Products

Milk and dairy products have had a number of roles. Much of the supply has been from cows; that from ewes and goats has been minor. Milk has always been an important element in the rural diet. In urban areas and near towns, the supply was traditionally inadequate, though small town dairies filled a gap. Supplies had a seasonal fluctuation. Milk could be processed into dishes such as Corstorphine cream, made from frothed whey. Cheese-making enabled surplus quantities of milk to be utilized, especially in districts located away from centers of population. A large number of regional recipes and varieties exist, some developed during the expansion of the dairy industry in the nineteenth century. The Highlands are associated with soft cheeses for rapid consumption such as crowdie; the Lowlands have longer-keeping hard cheeses. Butter was the only source of fat in the rural diet, though beef or mutton fat could be obtained.

### Meat, Fowl, and Fish

Meat was a foodstuff associated with social status. Among the rural population in the 1790s, it was rarely eaten. Even by the 1840s, it was still not an everyday foodstuff, especially among the poor. Before the Agricultural Revolution, livestock were slaughtered at Martinmas (November 11) as not all animals could be overwintered. Meat from domesticated livestock was supplemented by wild game and animals such as rabbits and hares. Sea fowl was caught in coastal areas. The nobility consumed large quantities of meat, especially on days when rents were

paid: payment was made in-kind, of which livestock formed a major element.

There were regional variations in the types of meat consumed. The keeping of pigs became prevalent with the spread of potato growing in the eighteenth century. At that time, mutton became a meat of social distinction, being confined to the higher classes in the Lowlands, and the lower classes in the Highlands and Islands.

All parts of animals were utilized, as food, or as non-food items, such as tallow for lighting or hides and leather goods. Mealy puddings were made from entrails; blood was mixed with oatmeal to form blood puddings (black pudding); heads and trotters from sheep were made into pie and soup stock (powsoddie). Meat was rarely eaten fresh. It was salted, dried, or pickled in brine.

Fish was primarily eaten in coastal regions. With the improvement of transport networks in the nineteenth century, consumption spread to inland regions. Fish was a central element of the diet: it was a subsistence food, it filled the hungry gap before harvest when food was in short supply, and it was a delicacy. The Western Isles and Islands had large quantities of herring, haddock, whiting, and mackerel. Other fish included salmon, cod, ling, and shellfish such as cockles and oysters; around the Orkney Islands, whale was plentiful. Coalfish was widely eaten among the working classes. Inland fish such as trout were caught. Fish were eaten fresh, dried, or smoked. A number of fish dishes, many local in nature, are food identity markers: kippers, salted and smoke-cured fish, usually herring, first developed in Newcastle in the 1840s; salt-pickled herring or Finnan haddock, a lightly salted and smoked haddock; Arbroath smokies, salt-dried and smoked haddock.

Birds and poultry include domestic poultry, especially hens and geese. Their eggs were eaten, as were those of wild fowl. In some districts such as Ness, in the Outer Hebrides, wild bird flesh was eaten from gannets.

Some foods have become associated with geographical areas (see Table 1).

### Beverages

The traditional drink crop was bere or barley. Ale was drunk, especially in Lowland areas; in the Highlands, whiskey was distilled, both legally and illicitly. Hot drinks spread from the upper classes. Tea drinking started to become increasingly widespread by the 1790s, though for some time afterwards it remained a drink for special occasions among lower social classes. Cocoa was drunk, as were coffee substitutes such as chicory. Coffee was not a drink of the working class, and even among industrial workers in Edinburgh in the 1950s it was consumed rarely, if at all. In recent decades coffee has increasingly taken the place of tea, among all social classes.

### Special Foods for Special Occasions

Special foods were eaten during festivals. They were specially prepared; they often had ingredients with a certain

**TABLE 1**

Area	Foods and dishes
Edinburgh and the Lothians	Midlothian oatcakes Edinburgh rock (sugary confection)
Angus and Fife, Forfar	Bridies (pastry filled with steak), Dundee marmalade, Dundee cake, Arbroath smokies, Pitcaithly bannock
Glasgow and Clydeside	Glasgow broth
Ayrshire	Cheese and Ayrshire shortbread
Borders	Selkirk bannock (rich yeasted bannock with sultanas and raisins); Eyemouth fish pie
Dumfries and Galloway	Galloway beef
North-East	Butteries, Finnan haddock, Aberdeen Angus steak, skirlie
Highlands and Inner Hebrides	Fried herring, game soup, tatties and crowdie (potatoes and soft cheese), Highland oatcakes, Atholl brose (whisky mixed with oatmeal).
The Outer Hebrides	Whelk soup, barley bannocks, kale soup
Orkney and Shetland	Oatmeal soup, fried herring and onions, potatoes with milk, beremeal bannocks

significance (such as flour from the last sheaf) or were made with ingredients that were expensive, difficult to obtain, or not eaten at other times of the year. Some dishes were served only at a festive occasion, or during part of it, others were not.

Festivals took place around the Celtic Calendar. They were held at the quarters that marked the passing of one season to another (Beltane, Lammas, Whitsun, and Martinmas). Foods included bannocks and oatcakes. Others were associated with the Gregorian Calendar. Hogmany, New Year's Eve, on December 31, was and probably still is the most widely celebrated of all the calendar festivals. Many of its foods were sweet in nature. Shortbread was a rich textured biscuit of flour, sugar, and butter. This could be decorated with a sugar iced or embossed pattern. Pitcaithly bannock was decorated with crystallized lemon and orange peel, caraway comfits, and almonds. Black bun is a rich and spiced dried fruit cake enclosed within a thin casing of bread dough or pastry. During harvest, harvesters were given wheat bread and ale; harvest meals also celebrated the end of harvest.

Rites of passage had foods associated with them. These included many common foods, with special attributes, such as bread, cheese, bannocks, and whiskey.

### Meal Times and Menus

Meals had distinct patterns. Eating times were shaped by class, occupation, work hours, and days of the week. In rural areas meals were arranged around the feeding of livestock.

Three main meals were eaten: breakfast in the morning, dinner in the middle of the day, and tea or supper at

The traditional Scottish *quaich* or drinking vessel derives its form from the Late Antique *condy*, a drinking bowl without feet. The Gaulish god Lugh is often depicted holding a *quaich* in one hand, indicating that there may have been religious or ritual associations with this vessel in ancient Scotland and on the Continent. This ceramic *quaich* dates from about 1680. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

five or six in the evening. The main meal was dinner; supper was fairly light but could also be substantial. Although traditionally no food was eaten between meals, changing mealtimes led to the evolution of the high tea, taken in the late afternoon, around four o'clock. It filled the gap between dinner and the evening meal. It developed as tea drinking became popular, especially among the upper classes. By the 1890s sweet and chocolate biscuits were becoming popular additions to the high tea. Meals had a number of courses. Dinner was three courses: a soup, a main course, and what was called a pudding. This varied: if there was soup, there might be no pudding; if there was no soup, the pudding was more substantial.

The eating of dishes, especially the main meal, had a weekly cycle. Sunday, the Sabbath, was reserved for churchgoing for Protestants and Catholics. (Other faiths had their Sabbaths on different days.) On this day meat was eaten. It was roasted, served with dumplings, and accompanied by potatoes and cooked vegetables. The by-products and leftovers of the Sunday dinner were eaten throughout the working week.

Menus of daily meals are recorded in household accounts, personal and travel diaries, letters, and cookery books. According to Alexander Fenton, house-servants in the 1790s had "breakfast of oatmeal porridge or sowens with milk; dinner of broth and boiled meat warm twice a week, or of re-heated broth, or milk, with cold meat, or of eggs, cheese, butter, and bread of mixed barley and pease-meal; supper was for breakfast, or in winter there might be boiled potatoes mashed with a little butter and

milk" (*Scottish Country Life*, p. 170). Ian Carter notes that in North-East Scotland during the 1840s, "the usual food of the farm servants [farm workers] is porridge and milk for breakfast: for dinner, potatoes, bread and milk with perhaps oatmeal brose made with greens, for supper. They do not have beer, except when there is a deficiency of milk. In harvest time an allowance of beer is given then" (*Farm Life in Northeast Scotland*, 1979, pp. 132–133).

Food and the diet have been influenced by a number of factors. Agriculture and changes within it led to changes in agricultural practices and the introduction and spread of new crops and markets. These affected the crops and livestock raised, their quantities, and seasonal availability. Trade and contact with other countries introduced foods, dishes, food habits, names of dishes, and methods of cooking. These were especially noted from the Netherlands during the sixteenth and seventeenth centuries. Political and cultural links have been important, like those from the Auld Alliance with France, which started in the eleventh century and had its greatest impact in the seventeenth and eighteenth centuries. It introduced dishes cooked "in the French way," such as "beef alamonde," dishes such as "omlit of eggs," terminology such as "gigot," a leg of mutton or lamb, and cooking utensils such as the "asht," a dish for serving meat.

### Union with England

Scotland was politically influenced by its larger neighbor, England. The two countries were joined in 1603 by a union of Crowns, then a Union of Parliaments in 1707. These brought the countries closer and shifted the power structure. The English Court influenced the food and eating habits of the nobility. Cultural influences came from the English diet and the introduction of such dishes as roast beef, mutton, and lamb.

Immigrants influenced the native food culture. From those of the sixth to the twelfth centuries, the Scandinavians influenced the use of resources from the sea and introduced dishes such as fish and mustard. Large-scale immigration took place in the nineteenth and twentieth centuries from Ireland, Italy, and India. Italians were noted for fish and chips and ice cream, with all their traditions of these foods. Italian specialty shops such as Valvona and Corolla are a noted feature of some cities such as Edinburgh, where there is a large Italian population.

Social changes created a demand for new foods. Food substitutes, such as margarine, developed around 1870, allowed for greater variation in the diet. So too did new methods of food preservation, such as canning, from the 1860s; refrigeration was first applied to meat imported from the United States in the 1880s; pasteurization was first used in the dairy industry around 1890. These also reduced the influence of season and locality.

## WALES

Archaeological and documented evidence show that the early Welsh economy was based on mixed farming. When journeying through Wales in 1188, Giraldus Cambrensis (also known as Gerald de Barri or Gerald of Wales) noted that most of the population lived on its flocks and on milk, cheese, butter, and oats. Numerous references to foods in literary works establish that this was generally how the Welsh subsisted until well into the nineteenth century.

### Ingredients of the Traditional Diet

The Report of the Royal Commission on Land in Wales (London, 1896) shows that small farmers and tenants survived on home-cured meat from domestic animals, home-grown vegetables, dairy products, and cereal-based dishes. Farmers and cottagers would fatten and slaughter at least one pig a year to provide a constant supply of salted bacon. On larger farms, a bullock or barren cow was also butchered and the meat shared between neighboring

Traditional Welsh cakes were baked in a small reflector oven on the hearth. The bottle jack to the right of the mantelpiece was used for roasting meat. COURTESY OF THE NATIONAL MUSEUM OF WALES.

farms. Keeping cattle provided sufficient milk to produce butter and cheese; vegetables were grown in the kitchen garden and fields, mostly leeks, carrots, cabbages, herbs, and, from the eighteenth century onward, potatoes. Wild fruits, plants, berries, wild animals and birds were utilized in season, and communities living close to coastal regions varied their diet by fishing and collecting shellfish such as cockles, mussels, periwinkles, and limpets. Inhabitants along the coastal regions of the Gower peninsula, Pembrokeshire, and Anglesey gathered the edible seaweed laver (*porphyra umbilicalis*). Prepared as a commercial product by Glamorgan families, it was sold along with cockles and mussels in the market towns of south Wales, famously Pen-clawdd. It was usually tossed in oatmeal and fried in bacon fat; today laverbread is a recognized Welsh delicacy, sometimes known as Welsh caviar.

### Traditional Dishes

The topography determined that oats and barley were the most commonly grown cereal crops, with wheat confined to the fertile lowlands. Oatmeal in its various forms was one of the basic elements in the diet of the Welsh. *Llymru* (flummery) and *sucan* (sowans), consisting of oatmeal steeped in cold water and buttermilk, boiled until thickened and served cool with milk or treacle, as well as *bwdram* (thin flummery), *uwd* (porridge), and *griwel blawd ceirch* (oatmeal gruel) were among the everyday fare served in most rural districts until the early twentieth century. The bread most regularly eaten throughout Wales until the late nineteenth century was oatbread, formed into wafer-thin circular loaves and baked on a bakestone or griddle over an open fire. It was used in the counties of north Wales as a basic ingredient in cereal pottages such as *picws mali* (shot) or *siot* (shot); a popular light meal consisting of crushed oatbread soaked in buttermilk. Brŵes (*brose*) was a common dish in the agricultural areas of the north and regularly prepared as a breakfast dish for the menservants. It was made from crushed oatbread steeped in meat stock and sprinkled with crushed oatbread before serving.

Welsh rural society was largely self-supporting with the exception of sugar, salt, tea, and currants, which had to be purchased. Sundays and special occasions usually merited a roast dinner for which a joint of fresh meat would be purchased from the local butcher; this was followed by homemade rice pudding. Very little fresh fruit was purchased, and eggs were eaten only on very rare occasions. The limited range of supplies also demanded great resourcefulness to provide an assorted menu. The ability to prepare an assortment of stews from one basic ingredient, namely oatmeal, required considerable dexterity. Similar skill was required for broths such as *cawl* and *lobsgows* using home-cured meat.

The open fire with its many appliances was central to cooking throughout the eighteenth and nineteenth centuries, and, in many rural homes, well into the twentieth century. Such limited cooking facilities also gov-

erned what could be prepared. Stews, joints of meat, and puddings were boiled in a cooking pot or cauldron. Pot ovens were used for roasting meat and baking cakes and fruit tarts, and the bakestone was widely used to bake oatcakes, drop scones, soda bread, pancakes, and griddlecakes (such as Welsh Cakes). Additionally, spits, Dutch ovens, and bottle-jacks, clockwork implements in the shape of a bottle that were hung in front of the fire, were used for roasting meat.

The preparation and consumption of traditional foods were closely integrated with patterns of life in rural Wales. Before labor-saving agricultural machinery, farmers were dependent on the cooperation of their neighbors to fulfill seasonal work. Corn (grain) or hay harvesting, corn threshing, and sheep shearing were essentially communal efforts requiring communal meals and celebrations. By the end of the nineteenth century, the *Boten Ben Fedi* (harvest pie), consisting of mashed potatoes, minced beef, bacon, and onion was served for the corn harvest supper. Threshing and shearing days were also marked with plentiful meals of cold lamb or beef, potatoes, and peas followed by rice pudding for dessert. *Tatws popty*—beef, onions, and potatoes—was a favorite in parts of Gwynedd, and afternoon tea consisted simply of home-baked bread, butter, cheese, and jam; while rich yeasted fruitcake and gooseberry pie were considered as shearing specialties in most regions.

In the industrial towns and villages during the late nineteenth century and early twentieth century, wives would often help to support their families in periods of hardship by preparing and selling home-cooked dishes, considered delicacies by members of the local community. Coal-miners' wives or widows prepared dishes of minced seasoned liver and pork fat called *faggots*, which were served with peas and sold from the women's homes or from market stalls. Pickled herrings were a comparable savory dish sold by women in the slate-quarrying communities of north Wales and consumed with home-made oatcakes by quarrymen and farm servants.

Although the tradition of living off the land survived until a later period, in the rural areas change came with improved roads, modern shopping facilities, refrigerators, and freezers. By the early twenty-first century, the majority of the above-mentioned dishes are mostly eaten on special occasions as traditional food.

**BROASTING.** "Broasting" is a trademarked term for frying chicken, potatoes, and other food in a pressure cooker using equipment and ingredients obtained under license from the Broaster Company of Beloit, Wisconsin. More broadly speaking, pressure frying is a technique for frying foods in oil under pressure, which is intended to seal the surface of the food and hold in its natural moisture while producing a crisp exterior.

Broasting is found only in food-service settings, since Broaster Company sells equipment and ingredients and licenses its name and program only to retail operations, such as restaurants, fast-food outlets, and grocery stores. Broaster Company, which was founded in 1954, had about five thousand licensees in 2002. Pressure frying is also used by some of the larger food-service operations, such as KFC (formerly known as Kentucky Fried Chicken) and Chick-Fil-A. These companies do not use the term "broasted," however, since it is trademarked by Broaster Company.

Pressure frying can be attempted at home using special equipment. The manufacturers of pressure cookers, however, do not recommend using them as pressure fryers. Manufacturers specifically advise the user not to put

more than  $\frac{1}{4}$  cup of oil in a pressure cooker, which is less than needed for frying. Use of a large amount of oil under high heat can damage the pressure seal of the lid and lead to the escape of steam or hot oil. A few companies manufacture units specifically designed to contain hot oil under pressure, and only these pressure fryers should be used at home.

Commercial units use gas or electricity to heat oil in a fry pot sealed to hold in steam. The pressure builds up to about fourteen pounds per square inch, with the food reaching an internal temperature of approximately 250°F (120°C) as compared with the 215 to 220°F (about 100°C) that occurs in conventional frying. Cooking time is reduced nearly in half as compared to conventional units, which is a significant advantage in the quick-service setting. A single unit can cook several racks of pork ribs in one batch in seven minutes, for example.

If all goes well, the cooked product will retain less than half as much oil as food cooked in a conventional open fryer. It is believed that this occurs because natural moisture escapes through the oil in the form of steam in conventional frying. In pressure frying, steam is locked into the fry pot, and natural moisture is forced to stay inside the food, which also prevents oil from getting in and producing a greasy product. Beck Sales Company, which makes the Fagor Classic brand of pressure fryer for home use, says its fryer will produce chicken with 44 percent more moisture than open-fried chicken, with 40 to 70 percent less fat and fewer calories.

The pioneer in pressure frying was "Colonel" Harland Sanders, founder of Kentucky Fried Chicken (KFC). At his restaurant in Corbin, Kentucky, Sanders sold fried chicken prepared in the traditional southern method of frying in a skillet. He preferred this to deep-fat frying because skillet frying produces a less-greasy product, but the method takes considerably longer than deep-fat frying. When the pressure cooker was marketed in the late 1930s as a time-saving device, Sanders purchased one and experimented with using it as a fryer. He eventually came up with the right combination of time, pressure, amount of oil, and temperature, and he began to use a pressure cooker in his restaurant. By the twenty-first century, all KFC restaurants used pressure frying to cook the company's Original Recipe Chicken. Various KFC outlets use several different types of pressure cookers.

The procedure specified by the Broaster Company is typical of pressure frying operations. The chicken is marinated and breaded, in both cases with proprietary ingredients, and oil is heated in the fryer pot to 360°F. A stainless steel basket is then lowered into the boiling oil, and pieces of chicken are loaded, up to fourteen pounds per load. Since dark meat takes longer to cook, thighs are loaded first, followed by legs, breasts, and wings. The cover is then locked in place, and the pressure valve is closed, allowing pressure to build up quickly. The

chicken is cooked at 360°F for eight to nine minutes, at which time the pressure valve is opened to release the steam, the cover is removed, and the chicken is drained.

It is considered important to keep the oil in the pressure fryer as clean as possible, which can be a problem when breaded products are cooked. Loose breading can create smoke and an off flavor due to the intense heat of the operation. Commercial units therefore have systems that recirculate the oil and filter out breading, carbon, excess moisture, and other impurities. This also extends the useful life of the oil. Steam can be used to force the oil out of the cooking pot and into the filter at the bottom of the cooker when the cooking cycle is completed, thus reducing the oil retained in the food and also lessening the chance of injury from hot oil when the pressure is released and the pot is opened. Pressure frying is safe when conducted according to manufacturer's instructions, but some units are equipped with built-in fire suppression systems. These systems, plus the heavy-duty construction needed for pressurized operation, make pressure fryers more expensive than conventional open fryers. Generally, pressure fryers are found only in restaurants that sell large amounts of fried chicken or other fried items.

While chicken is the best-known product in broasting or pressure frying, other foods can also be cooked in the same type of unit. Broaster Company provides its licensees with recipes, cooking instructions, coatings, seasonings, and marinades for potato wedges, catfish, pork chops, ribs, fish, shrimp, and mushrooms, among other items. While pressure frying normally uses fresh food, frozen items can also be pressure fried successfully. The finished chicken product should have a crispy, golden-brown exterior and should be tender and juicy throughout.

**BROCCOLI.** *See* **Cabbage and Crucifer Plants.**

**BROILING.** Broiling is a dry-heat method of oven cooking meats and vegetables in which the food is exposed to direct, radiant heat from a gas or electric element at about 550°F. The food is placed in a special pan and set several inches below the heating element until the desired state of doneness is achieved. Because little or no fat is added, broiling is considered a good method of cookery for those who are counting calories.

In Europe, broiling is considered virtually synonymous with grilling, but in America, the term “broiling” is usually applied to cooking in an oven, while “grilling” usually denotes the use of an outdoor or indoor grill.

In broiling meat, the objective is to sear the outside of the piece and seal in its natural juices or moisture, producing a browned, crusty exterior while bringing the interior to the doneness desired by the cook. In beef, this ranges from a state so rare that it appears to be tinged blue, to “well done,” with no hint of pink. The classic beefsteak is cooked medium rare. Beefsteak, pork chops, chicken, and fish are the most commonly broiled foods, but a wide variety of foods can successfully be broiled, even fruit, such as bananas.

Broiling uses a sturdy, two-part pan that fits well in the oven and is normally provided with the oven when new. The top part is the cooking surface and is slotted to permit juices to drip into the bottom part, which can be lined with aluminum foil to make cleaning easier. Either gas or electric heating elements can be used. While restaurants almost always use gas, many home kitchens are equipped with electric broilers. An electric broiler can be an advantage for some foods, such as fish, for which a temperature lower than 550°F is desirable, since the broiler can be set to the desired temperature. Some, but not all, gas broilers can be similarly adjusted.

Since heat rises, it may seem odd that the food is put under the heating element. However, broiling works by radiant energy, in which the heat is applied directly from the gas flame or red-hot electric element, rather than by convection, in which hot, moving air carries the energy.

While the broiler should always be pre-heated for ten to fifteen minutes before the cooking begins, the broiling pan should be left out so that the food is put on a cold surface and then put in the oven. This is to ensure that the food is cooked on one side at a time; otherwise, a hot pan would begin an inadequate cooking process on the “down” side before the piece is turned and becomes the “up” side, exposed to the heating element.

No moisture is added in broiling. To assist in the browning process, however, a thin film of oil can be brushed onto the food piece. Salt and pepper should be added after each side is cooked, but not before; salt can draw out moisture and slow down the browning process, while pepper will burn at high temperatures.

Before broiling beefsteaks and pork chops, most of the external fat should be trimmed, since it will create smoke and contribute nothing to the cooking of the meat. (The juiciness of beef comes from the internal fat known as marbling and a substance called myoglobin rather than from its external fat.)

### Basic Technique

Adjust the rack so that the surface of the food will be the desired distance from the broiler (see “Position,” below). Keep in mind that the pan and the food together will be

“Broiling” used to mean bringing food into contact with an open flame. The term has been largely replaced by “grilling.” These Thai sausages are being broiled on a broiling screen in Lap Lae, Thailand. © MICHAEL FREEMAN/CORBIS.

two or three inches deep at least. Slash the external fat vertically at several points to keep the steak from curling up as the fat shrinks. Place the food on the broiler pan and put it in the oven; sear one side, add salt and pepper to the cooked side, and turn the piece to cook the other side. Remove when the desired state of doneness is reached; let stand for a few minutes to allow the juices to settle, and serve with sauce or a pat of butter.

**Position.** The distance of the food piece from the broiler depends on the thickness of the piece. Pieces of meat that are an inch or less thick should be placed about two or three inches from the broiler, with thicker cuts set farther away. Very thick steaks (three or four inches thick, such as a filet mignon) should be broiled on one side about four inches from the broiler, and then the pan should be moved to a lower rack, eight or nine inches from the boiler, to finish.

**Time and doneness.** While a well-done steak was once considered a mistake if not a tragedy, many restaurant patrons and home cooks have come to tolerate this cooking method. The reasons for this may have to do with the fact that the best steaks—those labeled “prime” according to the grading system of the U.S. Department of Agriculture—are expensive and sold mainly to restaurants or high-end food stores, so that most supermarket shoppers have little acquaintance with steaks whose flavor is at its peak before they are thoroughly cooked. Also, some people believe that undercooked steak is dangerous. In fact, harmful bacteria, if present at all, are present only on the surface and are quickly destroyed by the heat of normal cooking. Deep muscle meat is sterile except under very unusual circumstances, such as extreme illness in the animal, or mishandling of the food. This observation does not apply, however, to hamburger,

Shown here is a handheld double broiler used for broiling fish, sausages, oysters, and small pieces of meat. The broiler was called "double" because it could be flipped over so that food could be cooked on both sides. From a wood engraving, circa 1880. ROUGHWOOD COLLECTION.

which consists of ground meat that could include contaminated portions; the USDA recommends thorough cooking of hamburgers and other ground meat products.

The timing for beefsteaks of about one inch thick, placed two inches from the broiler is: very rare, one to two minutes per side (the interior will be purple with a hint of blue); rare, two to three minutes per side (red inside); medium, three to four minutes per side (pink in the center); well done, broil three minutes per side, then lower the rack several inches and cook six to ten minutes more (the steak will be grayish or brown all the way though).

**Suitable foods.** Beef cuts suitable for broiling include the tenderloin or fillet (the center part is used for châteaubriand, and the tip is the filet mignon); rump

steaks; flank steak (for London broil); sirloin, rib-eye, and round steak.

Chicken legs, thighs, and wings can be broiled. Bone-in chicken breasts, as a result of their bulk, are better roasted or grilled in the oven; boneless chicken breast, however, is perfect for the broiler. The pan should be coated with oil to keep boneless breast from sticking, since it has almost no fat of its own.

Broiling is a good method for pork tenderloin but can easily dry out leaner cuts, such as pork chops, which usually benefit from cooking in liquid on the stovetop. Lamp chops broil well but will cook very quickly, taking two or three minutes per side for medium rare.

Fish fillets are thin enough to be broiled on a single side. Whole, cleaned fish (such as bluefish or mackerel) and fish steaks (such as salmon or tuna) can be broiled on both sides. A whole fish should have the head and tail left on for cooking and should be slashed in two places in the thickest part of the fish to let the heat reach the middle.

Some fruits and vegetables can be broiled, including asparagus; firm tomatoes, cut in half; and peppers. Broiling separates the skin from the pepper, leaving soft, cooked meat. Broiled grapefruit and bananas make tasty side dishes or desserts. Grapefruit, cut in half and topped with sugar, can be broiled until bubbling. Bananas can be peeled, cut lengthwise, and dotted with butter and sugar before broiling.

**BUDDHISM.** Buddhism originated in India in the fifth century B.C.E. and from there spread to many lands. The historic Buddha, born around 563 B.C.E., spent most of his eighty years traveling throughout north India preaching the way to salvation by reaching Nirvana and the cessation of rebirths. In some Buddhist traditions, respect for earth deities continues as a reflection of earlier cults of the soil. Animal sacrifices can still be seen in rituals requesting a boon from deities, ancestral spirits, and guardian spirits of localities. Food offerings may be left at stone monuments often containing relics commemorating the life and teachings of the Buddha. But these food practices are not Buddhist.

Buddhism is divided into several branches or ordination traditions. The Mahayana tradition, based on Sanskrit texts, spread into China, Korea, Vietnam, and Japan. The Buddhism of Tibet, Nepal, and Mongolia is also known as Vajrayana. Theravada Buddhism, “the way of the elders,” is the form of Buddhism found in Sri Lanka, Burma, Thailand, Laos, and Cambodia. It is based on Pali texts. More recently, Buddhism has spread to Europe, Australia, and North America, where people are converting in large numbers, partly out of interest in Buddhist meditation practices.

### Food Rituals

Food rituals transmit collective and individual messages about religious principles. Religion influences dietary intake by prescribing or proscribing certain foods, providing ritual foods or meals, and reinforcing key cultural and social values. Unlike Hinduism, Islam, and Judaism, Buddhism has less rigid dietary laws defining what people can eat and with whom they can dine. However, fasting and feasting are integral parts of most religious traditions, and Buddhism is no exception. The special foods used in the annual cycle of Buddhist holidays and festivals differ by country. Food is both a marker of religious affiliation and a marker of ethnic identity. It is therefore impossible to identify foods as specifically Buddhist, as opposed to Thai Buddhist or Japanese Buddhist, for example.

In rice-growing Asian communities where Buddhism is practiced, food in rituals reflects the rhythms of food production, including its scarcity or abundance during the year. In some countries, it is possible to see a contrast between ascetic approaches to food (for example, during the rains’ retreat from July to October) and festive excess (for example, after harvest in November and December).

Food rites mark changes in personal status as well, serving as temporal boundary markers through the life cycle. Special foods may be prepared for birthdays, weddings, funerals, tonsures, and ordinations, for example, particularly if monks officiate. In Theravada traditions, some of these rituals are Brahmanic in origin and feature rice and milk-based dishes. Harvest celebrations also make confections from foods such as rice, peanuts, sugar,

The kneeling women are giving donations of rice to a procession of monks in Luang Prabang, Laos, March 1993. The monks collect rice every morning. © MICHAEL S. YAMASHITA/CORBIS.

sesame seeds, and coconut, possibly related to the sweet offerings of South India, called *panchakadjaya* (five foods). Puffed rice is used at funerals to symbolize rice that cannot be grown again.

### Monastic Traditions

Dietary abstinence relates to a very widespread idea that giving up something desirable increases spiritual potency. In many religious traditions, food refusal also represents a denial of social relationships, a denial of sociability. Fasting is not central to Buddhist practice except for the monastic community. Most Theravada monks eat only once or twice a day, in the early morning and just before noon, as a part of monastic discipline and their dedication to following the path of the Buddha. The Sanskrit term *sambhogakaya* refers to the monastic practice of eating together. Theravada monks fast after noon and all night, often joined by pious laypersons who partially withdraw from the lay life of the householder on special holidays.

Monks are expected to show moderation and control in all things, including eating. They are warned that wrong mental states easily come to the surface when collecting or eating food. When Theravada monks go on begging rounds, giving people an opportunity to put food into their bowls, they are expected to show no interest in the qualities of the food and even mix the food donations together.

Chinese Buddhism regulates communal meals as part of monastic discipline. Rather than food being collected

from begging or donations as in Theravada communities, food in Chinese monasteries is often prepared at the temple by lay devotees. Mahayana monasteries used to grow their own food to provide vegetables for simple meals with rice or rice porridge. Occasionally lay donors might provide a vegetarian feast to celebrate Buddha's birth, enlightenment, and death, or *parinibbana*, in order to gain merit.

Zen cooking (*shojin ryori*) is a style of vegetarian cooking developed by Zen monks that acts as an aid to meditation and spiritual life. Food is prepared as a spiritual exercise with attention to balance, harmony, and delicacy. Some Zen and Chinese Mahayana temples practice the three-bowl eating style, making eating a ritual training. The three bowls contain rice, vegetables, and soup. In fact, eating can be a kind of meditation—remembering to let go of evil, to cultivate good deeds, and to save sentient beings—as each food is put into one's mouth. In such events, food is consumed according to need with no waste and no overconsumption.

Theravada Buddhists believe that by feeding monks they obtain religious merit that assures them of a good rebirth. Laypeople advance on the path to Nirvana by striving for moral purity and doing good works, especially by giving food to the monks. People also believe that giving food to the monks transfers merit to the dead. By going to the temple on the holy day and giving food to the monks, people hope to help their dead relatives who may be wandering the earth as hungry ghosts or living in hell.

### Food as Metaphor

Food is often used in Buddhist texts to explain complex ideas in an easily understood manner. Buddhism rejects the asceticism of fasting and denial found in many religious traditions. After the Buddha fasted for six years, he rejected the extreme of starvation as a route to salvation. Instead, he used the experience of eating and digesting food as a means to understand the instrumentality of food. The element of heat transmutes food into body during the process of digestion. Thus, eating is an important metaphor for understanding bodily existence and the transformation of matter and substance. Eating literally makes us human and embodies us.

The Buddhist path is the middle way requiring monks and laity to eat to maintain life and nourish the body but not to cling to the sensual pleasures of eating. In this philosophical interpretation, it is not material substances such as food that block salvation but the craving for them. When Buddhists gain right understanding, they can use this analytical knowledge to guide daily life, as well as for meditation. Food as an object of meditation is a metaphor for the foulness of the body. Monks concentrate on the repulsiveness of food in order to reduce their craving for food. The cessation of craving food is equated with the cessation of the body and the end of the cycle of rebirths.

### Commensality

For the laity, eating, particularly eating rice, is a means of orienting oneself in relation to all sentient beings whose lives are sustained by food and religion. Reciprocal food giving sustains lay communities as well as the monastic community. In general, Buddhist rituals imbue food with sanctity; the sanctity remains in the food after it has been received by the monks. Communal eating is one means of experiencing Buddhist precepts and concepts in a direct and sensory way.

In some Buddhist communities, members of the laity serve monks and the community by preparing and serving food from a communal kitchen. Mahayana services and ritual events are likely to be vegetarian. Most Chinese gods and goddesses are presumed to be vegetarian, but they may be offered meat in an attempt to provide the best, most valued food. Chinese Buddhism honors a number of deities, such as Kwan Yin, the Goddess of Mercy. A home altar might contain incense, flowers, tea, and fruit to be consumed later. The Kitchen Goddess helps one eat and drink healthily, and representations of her may be seen in household and restaurant kitchens.

Food given to Chinese deities is considered blessed; its essence is consumed by gods and Buddhas before it is eaten by the worshipers. Following chanting services in many temples, a communal meal is served, which may include beans, bean sprouts, vegetables, fruit, and always rice for prosperity.

### Food Distribution in Theravada Communities

Four times in the lunar month, or weekly, the following practices might be seen repeated in Theravada communities throughout the rural areas of Southeast Asia. On a holy day, people bring such food as rice and dishes to eat with rice to the temple. Although the food is the best a household can prepare, people bringing the food cannot taste or even smell the food. A true gift that will gain religious merit must be well intentioned, and only by denying themselves even the smell of the food will the offering bear fruit. The monks chant to accept the food and confer blessings on those who have given food.

At the end of the morning service, after the monks have eaten, the laypeople consume the remaining food offered to the monks. By giving to monks who must follow rules of celibacy and denial, religious merit is increased at a greater rate. Generally, everyone who participates in the service shares in consuming the food that has been accepted or blessed by the monks. Even those who have not contributed food are actively encouraged to share the meal, as if the sharing of food may cause the intention to give generously to arise among all partaking of the meal. Following the meal, participants share the merit accrued from feeding monks with all sentient beings.

## Buddhism and Vegetarianism

Buddhism in North America is widely associated with vegetarianism, although not all Buddhists are vegetarian and vegetarianism is not part of canonical Buddhism. This association with Buddhism developed because the key principles of Buddhism include ahimsa, or nonviolence and the avoidance of suffering. Theravada Buddhists in Southeast Asia are not generally vegetarian, although their daily meals may not include much meat. Meat dishes are even given to monks since meat is not explicitly forbidden to them by the rules of monastic conduct. Buddhist texts such as the *Majjhima Nikaya* refer to the Buddha eating the proper proportion of curry to rice, experiencing flavor but not greed for flavor.

As more Westerners become Buddhist and as more Buddhist immigrants and refugees settle in North American and European cities, Buddhist vegetarian restaurants have prospered, offering devotees and secular vegetarians an opportunity to consume food exemplifying the Buddhist principle of nonviolence. Practicing Buddhist chefs prepare vegetarian feasts for events such as meditation retreats and cater meals for vegetarian practitioners and health-conscious diners. They may also perform *dana*, or selfless giving, by providing free food to the hungry.

Values of reciprocity and sharing are extremely important to Buddhists. In the strongly individualized and materialistic communities of North America, it is particularly difficult to maintain models of generosity and reciprocity. Commensality—the shared meal of Buddhist merit makers—is a model of reciprocity, redistribution, and generosity. The act of eating together and sharing each other's food is a concrete and reliable means of establishing a moral community where people know they can develop relations of trust with others and cooperate in joint activities within the domain of religion and in other domains.

**BUTTER.** Butter is made by churning milk fat. It has a solid, waxy texture and varies in color from almost white to deep yellow. It is mostly made from cow's milk, but water buffalo milk is used in the Indian subcontinent, yak milk in the Himalayas, and sheep milk in central Asia. Butter is an important food in North America, Europe, and western and central Asia but is of lesser importance in the rest of the world.

## Butter Making

Until the late nineteenth century, butter was made by traditional small-scale methods. Milk was "set" in bowls until the cream rose and could be skimmed off. It was used fresh for sweet cream butter or "ripened" (soured) as the bacteria it contained converted the lactose (milk sugar) to lactic acid. Sometimes clotted (scalded) cream was used, and milk fat retrieved from whey after cheese making can also be used for making butter.

Once or twice a week the cream was churned in a standing churn with a plunger or in a barrel turned end-over-end. Eventually, granules of butter separated out, leaving buttermilk, which was drained off and used for drinking and baking. The butter was washed and worked (kneaded with a paddle) to get rid of excess liquid, then salted. Butter-making implements were wooden; they included bowls, butter paddles, and prints carved with motifs, such as swans or wheat ears, used to stamp finished pats.

In modern industrial manufacture, cream is separated by a centrifugal process to give a fat content of 30 to 38 percent. It is always pasteurized, and ripening is induced by adding a bacterial culture. The cream is churned at a temperature of 53 to 64°F (12 to 18°C). High-speed continuous churns were introduced after World War II. In these the cream is mixed by revolving blades, which induces granulation quickly. The butter granules are forced through a perforated plate and are worked mechanically. Salt and annatto (coloring) are added if desired. About twenty liters of milk are needed to make one kilogram of butter.

## Physical Descriptions

The mechanism of butter production is not fully understood. The process inverts cream, an emulsion of minute fat globules dispersed in a liquid phase (water), to become butter, an emulsion in which minute drops of liquid are dispersed in a solid phase (fat). Churning first traps air in

## FLAVOR IN BUTTER

Flavor in butter is influenced by many factors. Two basic types exist in European and North American tradition: sweet cream, churned from fresh cream, with a mild, creamy flavor and ripened; or lactic butter, made from soured cream, which should have a fuller, slightly nutty flavor. Salt butter can be of either type. Regional tastes in this vary widely. In Europe, Welsh butter is noted for being very salty, whereas French butter is often not salted at all. Under modern conditions, salt is only added for flavor, its original preservative function now obsolete.

The characteristic butter flavor comes partly from the high proportion of short-chain fatty acids milk fat contains, especially butyric acid. Ripening gives a “lactic” flavor derived principally from a substance called diacetyl, produced by the bacterial species involved. In the United States, most butter has a mild lactic flavor, although it is stronger in “cultured” butter, which is closer to that produced in Germany and central Europe, where strongly flavored butters are preferred.

Differences in butter flavor were far more apparent in the past. Factors that influenced the flavor of farm-made butter included the food the cattle ate. Turnips, introduced as a fodder crop in eighteenth-century England, were notorious for giving a characteristic and much-disliked taint to butter. Some pastures, such as those of Normandy, are recognized as producing excellently flavored butter. Poor storage conditions for milk or butter also led to taints, as fats pick up odors quickly. Storage in rooms that also contained, for instance, onions was not recommended. Care during handling is also important. Length of ripening time, hygienic handling, and complete expression of the buttermilk from the finished product influence flavor.

Finally, from the moment it is finished, butter is susceptible to rancidity of two types. Hydrolytic rancidity is produced by the presence of moisture and is hastened by enzymes and microorganisms, and consumers have developed a taste for some forms. Oxidative rancidity, produced by reaction with oxygen in the air, is found unacceptable by everyone.

the cream, producing a foam. Continued agitation destabilizes the fat globules, disrupting the fine membranes that surround them and releasing naturally occurring emulsifiers such as lecithin. As agitation continues, the foam collapses, and the fat droplets are forced together in grains. Gradually they increase in size and become visible.

Finished butter has a complex structure of minute water droplets, air bubbles, and fat crystals distributed through amorphous fat. Proportions of solid and liquid fats present in butter vary. A lower churning temperature increases the proportion of crystalline fats, giving a harder, almost crumbly product. Higher temperatures produce a softer butter. Butter can also be whipped after churning to make it softer and easier to spread. Flavor is influenced by many factors (see sidebar).

Salt was originally added as a preservative. Butter made from unpasteurized milk is susceptible to bacterial spoilage. Even under modern conditions of hygiene, it is susceptible to oxidative rancidity. One way of extending shelf life is clarification, which includes two basic methods. One is to melt the butter gently and pour the fat off, discarding the milky residue. The second, used in India, is to simmer the butter until the water evaporates and the protein and milk sugar form a solid brown deposit. The fat, now with a nutty flavor, is strained off and stored as ghee, which keeps for months. Butter and ghee are significant in Indian cookery and Hindu religious ritual. In the Arab world *samneh*, a form of clarified butter, is also used for cookery. In Morocco it is mixed with herbs to make *smen*, a strongly flavored aged butter.

## Nutrition

Nutritionally the composition of butter is roughly 80 percent fat (mostly saturated), 12 percent water, 2 to 3 percent nonfat milk solids (lactose, protein), and 2 percent added salt. It is the most concentrated of dairy products, containing about 740 kilocalories per 100 grams (210 kilocalories per ounce). Butter is a valuable source of vitamin A, plus it has a little vitamin D. It is also a source of dietary cholesterol. Vitamin content is higher in summer, when the cattle feed on fresh grass.

Nutritional debates over saturated fatty acids and cholesterol in relation to coronary heart disease have centered on butter. High fat consumption can be related to raised blood lipids, but the relationship of dietary cholesterol to blood cholesterol is less easy to demonstrate. Evidence for or against is seized in the debate between butter and margarine manufacturers over which is superior. The two groups have competed since margarine was invented in the 1870s. Their arguments were originally couched in terms of economics but subsequently obscured important health issues. In the United States butter consumption stands at about 500,000 metric tons per annum, as opposed to the European Union, which consumes almost 1.5 million tons with only about one-third more population than the United States. Much of the difference is probably due to preferential consumption of margarine for perceived health benefits by U.S. consumers.

## Development of Production

Annual world production of butter (including ghee) rose from about 5.35 million metric tons in 1961 to about 7.551 million metric tons in 2001, during which time the

global population doubled. By the twenty-first century, India was the world's largest butter and ghee producer. Its production increased fivefold between 1961 and 2002, whereas the country's population increased about 2.25 times. The European Union, an area in which butter has enormous importance in traditional eating habits, is the next most important producer, followed by the United States. New Zealand, with a small population, produces much butter for export, but production in Canada, formerly an important exporter, has fallen.

The origins of butter are unknown. One theory is that migrating nomads discovered that milk they carried with them became butter (much as American pioneers

made butter by allowing the motion of the wagons to churn milk as they traveled). Butter has been known in Eurasia since ancient times, although the classical Greeks regarded it as barbarian food. Later friction arose over Lenten food prohibitions by the church in medieval Europe. Oil, a southern staple, was allowed, but butter, derived from animals, was forbidden, creating difficulties for northerners who had to buy expensive imported oil or pay a fine to use butter.

In northern and western Europe, butter was an integral part of the pastoral economy. It was churned from surplus summer milk and was stored in wooden barrels. Butter production was women's work and in many places,

such as early modern England, provided an income for farmer's wives, hence the frequency of Butter Market as a street name in English towns. Certain areas developed dairy food production as a specialty. By 1750 the Low Countries exported butter and cheese to neighboring regions. In Ireland butter is the most esteemed of all dairy products. In the Middle Ages it was used to pay taxes and was buried in peat bogs for preservation. Archeologists still find the occasional cache of "bog butter," which made Irish oat cake and later potatoes palatable. Migrants from the Low Countries, Britain, and Ireland took their taste for butter to North America, where observers remarked on the lavish use of it in cookery and at the table.

Creamery production of butter, in which milk collected from a large number of farms was taken to a central point for processing, began in the late nineteenth century. It gave benefits in economies of scale and quality control but reduced regional nuances. An important step toward the process was the introduction of a mechanical cream separator by Gustav de Laval in Denmark in the 1870s. In 1881 Alanson Slaughter built a creamery in Orange County, New York, using the milk produced by 375 cows. By 1900 a creamery in Vermont used the milk from thirty thousand cows to make over ten tons of butter a day, and the production of country butter de-

clined rapidly. Canada and New Zealand developed butter as an export commodity for the British market. Most butter produced in the developed world is made in creameries.

Butter is important in European food habits and cuisines derived from them. It is used as a spread for bread, crackers, and toast and to dress cooked vegetables and pasta. In baking it adds flavor and shortness to cakes and some pastries. Butter has a privileged position in French cookery, especially in sauces, such as *beurre blanc*, *hollandaise*, and *béarnaise*. It is not ideal for frying as the protein it contains burns at about 250°F (120°C), but clarified butter can be heated to about 375°F (190°C) and is often used for shallow frying fish. Butter or ghee also gives character to northern Indian food. For instance, a small amount heated with spices is added to pulse dishes for richness and to finish the cooking process. In Tibet butter is floated on bowls of tea, the residues of which are mixed with *tsampa* (barley flour) and eaten.

**BYZANTINE EMPIRE.** Constantine I, the first Christian emperor of Rome (reigned 306–337), established a new eastern capital in 330 at a site unrivaled for its beauty and unmatched as a center for administration and trade. The Greek colony of Byzantium had prospered on its exports of salted bonito and other seafood. Now renamed Constantinopolis (modern Istanbul), it was destined to be the capital of the later Roman or Byzantine Empire for eleven hundred years.

The civilization of Constantinople is sometimes misunderstood as a poor imitation of classical Greece and Rome. From the perspective of medieval western Europe, however, Constantinople was a city of magic and mystery. Early French epics and romances tell of the wondrous foods, spices, drugs, and precious stones that could be found in the palaces of Constantinople.

Byzantine culture never ceased to develop and to innovate, and this is certainly true of its cuisine. Among favored game were the gazelles of inland Anatolia, and wild asses, of which herds were maintained in imperial parks. The seafood most appreciated by the Byzantines was bo-

targo (salted mullet roe), and by the twelfth century they were familiar with caviar. Fruits largely unknown to the ancient world but appreciated in Constantinople included the aubergine (eggplant), lemons (via Armenia and Georgia), and the orange. The Byzantines were the first to try rosemary as a flavoring for roast lamb; they first used saffron in cookery. These aromatics, well known in the ancient world, had not previously been thought of as food ingredients.

Byzantine cheeses included mizithra (produced by the pastoral Vlachs of Thessaly and Macedonia) and Cretan prospathos. As for bread, the bakers of Constantinople were in a most favored trade, according to the ninth century *Book of the Eparch*, a handbook of city administration: “bakers are never liable to be called for any public service, neither themselves nor their animals, to prevent any interruption of the baking of bread.” Mastic and anise were among the aromatics used in baking.

The distinctive flavor of Byzantine cookery is best represented by sweets and sweet drinks. There are dishes that we would recognize as desserts: *groutha*, a sort of frumenty, sweetened with honey and studded with carob

seeds or raisins; and rice pudding served with honey. Quince marmalade had been known to the Romans, but other jellies and preserves now made their appearance, based on pear, citron, and lemon. The increasing availability of sugar assisted the confectioner’s inventiveness. Rose sugar, a popular medieval confection, may well have originated in Byzantium.

Flavored wines, a variant of the Roman *conditum* (spiced wine), became popular as did flavored soft drinks, which were consumed on fast days. The versions that were aromatized with mastic, aniseed, rose, and absinthe were especially popular; they are distant ancestors of the masticha, vermouth, absinthe, ouzo, and pastis of the modern Mediterranean. A remarkable range of aromatics, which were either unknown to earlier Mediterranean peoples or used only as perfumes or in compound drugs, were added to Byzantine spiced wines: spikenard, gentian, yellow flag, stone parsley, spignel, valerian, patchouli, storax, ginger grass, chamomile, and violet.

Two influences combined to produce the great range of powerful flavors at the heart of Byzantine cuisine. One was the Orthodox Christian church calendar,

with its numerous fast days on which both meat and fish were proscribed: the rich (including rich abbots and ecclesiastics) gave their cooks full rein to produce fast-day dishes as piquant and varied as could be imagined. Byzantine pease pudding, a fast-day staple, was aromatized with nutmeg, an eastern spice unknown to the classical Greeks and Romans.

The second influence was that of dieticians. Ancient Greek and Roman dietary manuals had been addressed to experts. The Byzantine ones, however, were written for nonspecialists. As in classical Greece and Rome, physicians relied on the theory of the “four humors” (blood, phlegm, yellow bile, black bile) and prescribed diets aimed to achieve a proper balance of humors in each individual. The effect of each ingredient on the humors was therefore codified so that the desired balance could be maintained by a correct choice of dish and by a correct adjustment of ingredients, varying for the seasons, the weather, the time of day, and each individual’s constitution and state of health. Dieticians sometimes recommended vegetarian meals, eaten with vinegar or other dressing. Spices and seasonings became ubiquitous, used both during the cooking process and at the table to amend the qualities of each dish. Fresh figs, if eaten in July, must be taken with salt. A daily glass of conditum, strong in spikenard, was recommended in March; anisaton, anise wine, was appropriate for April. These Byzantine dietary manuals are important sources of culinary history; bostargo is first named in the eleventh century by the dietician Simeon Seth, who notes that it “should be avoided totally.” The earliest work in this tradition is Anthimus’s *On the Observance of Foods*, compiled by a Byzantine physician for a gothic monarch in the early sixth century.

The food of the poor of Constantinople was no doubt limited, though a poetic catalog of a poor family’s larder (*Prodromic Poems* 2.38–45, probably twelfth century) includes numerous vegetables and locally grown fruits along with a considerable list of flavorings: vinegar, honey, pepper, cinnamon, cumin, caraway, salt, and others. Cheese, olives, and onions perhaps made up for a scarcity of meat. *Timarion*, a satirical poem of the twelfth century, suggests salt pork and cabbage stew as being a typical poor man’s meal, eaten from the bowl with the fingers just as it would have been in contemporary western Europe. The staple of the Byzantine army was cereal food—wheat or barley—which might be prepared as bread, biscuits, or porridge. Inns and wine shops generally provided only basic fare. However, in the sixth-century *Life of St. Theodore of Syceon*, a Byzantine text, there is a reference to an inn that attracted customers by the quality of its food.

Annual fairs were a focus for the food trade. Important fairs were held at Thessalonica and Constantinople around St. Demetrius’s day. Constantinople was known for specialized food markets. Sheep and cattle were driven to market to Constantinople from pastures far away in the Balkans, and eastern spices followed long-estab-

lished trade routes through Trebizond, Mosul, and Alexandria. The populist emperor Manuel (1143–1180) liked to sample the hot street food of the capital, paying for his selection and waiting for change like any other citizen.

Medieval travelers to Byzantium did not always like the strange flavors they encountered. Garos, the fish sauce of the ancient world, which was much used as a flavoring by the Byzantines, was unfamiliar and often unappreciated. Many disliked resinated wine (comparable to modern retsina), which was simply “undrinkable” according to one Italian traveler, Liutprand of Cremona. However, foreigners were seduced by the confectionery, the candied fruits, and the sweet wines. William of Rubruck, a thirteenth-century diplomat who was looking for presents to take from Constantinople to wild Khazaria, chose dried fruit, muscat wine, and fine biscuits.

The cuisine of the Byzantine Empire had a unique character of its own. It forms a bridge between the ancient world and the food of modern Greece and Turkey. In Constantinople astonishing flavor blends were commonplace. For example, roast pork was basted with honey wine; skate was spiced with caraway; wild duck was prepared with its sauce of wine; there was garos, mustard and cumin-salt, and black-eyed peas served with honey vinegar. Old recipes were adapted to new tastes; whereas ancient cooks had used fig leaves, *thria*, as edible wrappings for cooked food, during Byzantine times vine leaves were used in recipes, the precursors of modern dolmades.

When the future emperor Justin II (reigned 518–527) walked from his Dalmatian homeland to Constantinople in 470 as a penniless young man seeking service in the Imperial guard, we are told that he had nothing but army biscuits to keep him alive on his long march. This *paximadion*, or barley biscuit, makes the perfect link from the ancient, via the Byzantine, to the modern period. A classical Roman invention, popularized in the Byzantine Empire, it has many modern descendants: the Arabic *bashmat*, *baqsimat*, the Turkish *beksemad*, the Serbo-Croat *peksimet*, the Romanian *pesmet*, and the modern Greek *paximadi*.

Beyond the old boundaries of the Byzantine Empire, Byzantium’s greatest legacy to western cookery may be summed up in these four things: the table fork, which entered Europe through Italy; marzipan, which appears to have originated in Armenia (the word is of Armenian origin); the samovar, which moved northward into Russian culture via the Greek Church; and the Cult of St. Nicholas, together with the gingerbread cookies associated with this Christmas saint.

**CABBAGE AND CRUCIFER PLANTS.** The cole crops broccoli, brussels sprouts, cabbage, cauliflower, collards, kale, and kohlrabi belong to the same species (*Brassica oleracea* L.) in the Brassicaceae or mustard family. Kale most closely resembles the progenitor to this group of vegetables. Native to European coasts, wild *B. oleracea* and related species are one to two meters in height with large lobed leaves and a terminal inflorescence of yellow flowers. Different portions of the plant were emphasized during domestication. Broccoli and cauliflower were selected for large edible inflorescences, kohlrabi for an enlarged basal stem, and brussels sprouts and cabbage for leafy buds (axillary and terminal buds, respectively). These vegetable crops grow best in cool climates with adequate soil fertility and ample water. *Brassica* species are unique in producing glucosinolates, the compounds that impart pungency to various cole crops. Certain forms of these compounds are antinutritional while others are beneficial. On the balance, consumption of cole crops has a positive influence on human health. Cole crops are used fresh, may be canned, frozen, dehydrated, pickled, and fermented. Sauerkraut, made from fermented cabbage, is an ancient process that was used to preserve this vegetable as a source of vitamins and minerals during the winter months.

### Plant Biology

**Plant description.** The cole crops are members of the Brassicaceae family (formerly Cruciferae). This family includes over three thousand species in more than three hundred genera. Plants are usually herbaceous annuals, biennials, or perennials. Cabbage and related cole crops belong to the species *Brassica oleracea* L.

With exception of certain cabbages and some types of kale, this group has smooth, alternate leaves with lobed or wavy to highly dissected margins. Leaves may be thick and succulent, with or without a waxy bloom. Some types grow to over two meters on a shallow and fibrous root system. The inflorescence is a terminal raceme of showy yellow or white flowers. Flowers possess four perpendicular petals that the medieval Europeans thought resembled a crucifix (thus the former family name Cruciferae). Flowers also have four sepals, a two-celled, superior ovary with a single stigma and style, and six stamens, two of

which have shorter filaments than the others. The fruit (seed pod) is a silique with a persistent, beaked style. At maturity, siliques dehisce longitudinally to release the small round brown or black seeds. Seeds mature fifty to ninety days after fertilization. The species is insect cross-pollinated with self-pollination prevented by a sporophytic self-incompatibility system. All naturally occurring *B. oleracea* are diploid with nine pairs of chromosomes.

With the exception of some cauliflower and broccoli cultivars, the cole crops have a biennial reproductive cycle. Broccoli and cauliflower may be either annual or biennial (Table 1). Except for tropical cauliflowers, vernalization is required for flowering.

During domestication, different plant organs were emphasized. Kale and collards are the least modified from the ancestral form. Cabbage possesses a head composed of overlapping leaves formed on a shortened stem. Brussels sprouts form smaller heads in the leaf axils of the stem. The edible portion of kohlrabi is a shortened and swollen stem. Broccoli has been selected for an enlarged stem and inflorescence that is consumed when flowers are fully developed but have not yet opened. Like broccoli, the head of cauliflower is eaten. However, the head consists of a highly branched mass of undifferentiated shoot apices (curd) that only later may differentiate into floral primordia.

**Growth requirements.** The *B. oleracea* are cool season crops, with optimum growing temperatures of about 59–68°F (15–20°C), but plants will grow slowly even at 14°F (5°C). Cole crops are cold and frost tolerant, but developmental stage and type of crop affects the degree of cold tolerance. Young plants are more tolerant than are older plants, and crops whose vegetative parts are eaten are generally more tolerant of low temperatures than crops whose reproductive parts are consumed. Kale and brussels sprouts are the most cold hardy, and can withstand temperatures as low as 14 to 23°F (–5 to –10°C). High temperatures (>77°F or >25°C) will inhibit or impair head development in broccoli. Almost no broccoli cultivars can be grown in the warm tropics because plants fail to form heads. Winter, summer, and tropical cauliflower cultivars have been developed, each of which has a different optimal temperature range. For

summer types, the optimum temperature for curd development is 62 to 64°F (17 to 18°C) with small “button” heads induced at temperatures above 68°F (20°C). Some winter types develop curds even at 50°F (10°C) while some tropical types will tolerate temperatures up to 86°F (30°C).

**Botanical types and horticultural characteristics.** *Brassica oleracea* vegetables show amazing diversity in form that is reflected in the different botanical variety names assigned to them (Table 1). These names generally describe the origin of the crop, or the edible part that has been accentuated.

The cabbage group is differentiated based on head shape and color, leaf texture, and intended use. Savoy types, with crinkled leaves and looser heads, are used primarily fresh in salads. Smooth-leafed, firm-headed cabbages are used for fresh market and processing. Fresh market types are typically small-headed and may be green or purple. Fresh market types are further differentiated into those sold immediately, and those stored for several months before sale. Processing types (mainly used for sauerkraut) have large heads (up to 4 kg) that are high in dry matter. Cabbage heads can vary in shape from pointed, to round, to oblate.

Firm heads (which depends on the arrangement and thickness of leaves, leaf angle, and freedom from axillary cavities) are preferred. The core (main stem within the head) should be small in diameter and less than half the height of a mature head. A dark-green or purple external color is preferred for market. Fresh market and storage cabbage can have white, green, or purple internal color, but for sauerkraut, white internal color is essential. Uniform size and maturity are necessary for efficient harvest and packing.

While the term “broccoli” is commonly used in the United States to refer to *B. oleracea* var. *italica*, elsewhere this crop may be called “sprouting broccoli” or “calabrese” (after a landrace, or farmer-selected variety, from the Calabria district of southern Italy). Other crops that use the name “broccoli” are “broccoli rape” (turnip or *B. rapa* inflorescences), “heading broccoli” or “cauliflower broccoli” (*B. oleracea* var. *botrytis*), and “Chinese broccoli” (*B. oleracea* var. *alboglabra*). Broccoli may have purple or green heads, be single or multiple-headed, and have annual or biennial (winter type) habit. Cultivars also vary in plant height, head shape, size of flower buds, and stem length.

Important horticultural characteristics for broccoli include yield (which is related to uniform field matu-

TABLE 1

The cole crops, their uses and plant biology					
Crop	Species and botanical name	Part used as food	Flowering habit	Internodes elongate in first year	Temperature requirements for flowering
Kale	<i>Brassica oleracea</i> var. <i>acephala</i>	Leaves	biennial	yes	Approximately 6 weeks at 4.5°C after reaching a minimum stem diameter (3–4 mm)
Collards	<i>B. oleracea</i> var. <i>acephala</i>	Leaves	biennial	yes	Similar to kale
Cabbage	<i>B. oleracea</i> var. <i>capitata</i>	Leafy head or apical bud	biennial	no	Approximately 8 weeks at 4.5°C after reaching a minimum stem diameter (usually 6–8 mm)
Brussels sprouts	<i>B. oleracea</i> var. <i>gemmifera</i>	Axillary heads or buds	biennial	yes	Similar to cabbage; specific data not available
Kohlrabi	<i>B. oleracea</i> var. <i>gongylodes</i>	Fleshy stem	biennial	no	Little juvenile period; one week at 10°C sufficient to cause bolting
Cauliflower	<i>B. oleracea</i> var. <i>botrytis</i>	“Curd”	annual	yes	Summer and tropical varieties: Will form curds without cold and proceed to develop flowers. Late varieties may not have time to flower during growing season.
			biennial	no	Winter varieties: Low temperature exposure after about 6 weeks of age will cause curd formation; flowering follows without additional chilling.
Broccoli or Chinese kale	<i>B. oleracea</i> var. <i>italica</i>	Young inflorescence	annual	yes	Low temperature hastens heading but not required for head formation and flowering.
Kai lan, Chinese broccoli, or Chinese kale	<i>B. oleracea</i> var. <i>alboglabra</i>	Leaves, young inflorescence	annual	yes	Specific data not available

Cabbage figures prominently in the diet of Caribbean and Central American countries. These cabbage fields are in the mountainous region of Valle Nueva near Constanza, Dominican Republic. © RICHARD BICKEL/CORBIS.

rity, and head size and stem weight), and head and stem color (dark green is preferred for processing). Heads should be firm and supported by a deeply branched stem. Domed heads shed water and are less susceptible to head rot than are flat heads. Smooth heads are needed for fresh market, whereas processors prefer segmented heads. The individual branches or florets should be small, firm, and even in maturity and color. Small flower buds (called “beads”) are preferred. Defects include uneven flower bud development (“rosetting”), large bead size, loose heads, depression in center of the head, dead flower buds, leaves in head, and yellow color.

Cauliflower cultivars are differentiated mainly by maturity as previously described. Curds are commonly white, but may also be green, orange, or purple. Summer and some winter types have been selected for leaves that wrap tightly about the head to facilitate curd blanching, while tropical types may lack adequate wrapper leaves for self-blanching. For some cultivars, field workers must break or band the wrapper leaves to provide adequate

covering for the curd. Cauliflower is perhaps the most fickle of the cole crops to grow because of its exacting climatic requirements.

Important horticultural characteristics include head size (medium is preferred for fresh market, but it can be large for processing), head weight (less cavity space is better), and large, clasping wrapper leaves that prevent curd exposure. Yield depends on good cover, which permits heads to grow larger before exposure. Heads must be pure white for processing and fresh market. Uniform maturity is important but difficult to achieve, even in  $F_1$  hybrids. Over-mature heads will begin to show curd differentiation (“riciness”). Heads should be free from leaves.

Brussels sprouts are late maturing biennials. The main difference among cultivars is in stem length and maturity. Shorter types, while earlier maturing, also tend to be lower yielding than the tall types. For processing, sprouts should be firm and about 1.5 to 3 cm in diameter. Cultivars may have green or purple sprouts.

## CULTIVARS

The term "cultivar" is used to distinguish a kind of vegetable from a botanical variety. Cultivars are things like "Excelsior" broccoli or "Snow Man" cauliflower. Cultivars may be open-pollinated, pure lines or inbreds, or  $F_1$  hybrids. A botanical variety refers to a group of similar cultivars. For example, broccoli is classified as *Brassica oleracea* var. *italica* (the botanical variety of the cole family that comes from Italy). Sometimes the term "variety" is used interchangeably with "cultivar." For example, many garden seed catalogs use the term "variety." The terms "open-pollinated," "pure line," "inbred," and " $F_1$  hybrid" refer to the genetic structure of a cultivar. Open-pollinated varieties (often referred to as OPs) are usually a mix of genetically heterozygous plants forming a heterogeneous population. OPs are usually cross-pollinated and can be variable for horticultural traits. If a plant from an OP population is self-pollinated for several generations, it becomes an inbred line. With approximately six generations of self-pollination, a line will become genetically homozygous, and the population will be homogeneous. Crops that are normally self-pollinated (such as beans or peas) are called "pure lines" when inbred.  $F_1$  hybrids are developed by crossing two inbred lines. The cross must be repeated to produce  $F_1$  hybrid seed because selfed or crossed seed from the  $F_1$  hybrid will not breed true.  $F_1$  hybrids are genetically heterozygous but form homogenous populations.

**Cultivar types.** Cole crop landraces and cultivars were originally open-pollinated populations, consisting of genetically heterogeneous individuals. Such populations are

subject to inbreeding depression in subsequent growing seasons if the grower saves seeds from too few individuals. Some open-pollinated cultivars are still grown, but the majority of contemporary cultivars are  $F_1$  hybrids. Breeders develop inbreds, which are then planted in isolation in pairs to produce the  $F_1$  hybrid seed, relying on self-incompatibility or cytoplasmic male sterility to enforce outcrossing.

Isolation of one-half to one mile between seed fields is required to prevent unwanted cross pollination. Any combination of *B. oleracea* crops and their wild forms may cross with one another and produce contaminants in a seed lot. *B. oleracea* does not need to be isolated from *B. rapa*, *B. juncea*, *B. nigra*, *B. napus*, and *Raphanus sativus* because these species will cross only with great difficulty.

**Phytonutrient constituents.** The Greeks and Romans recognized the nutritional and medicinal benefits of cole crops. Today, cole crops are recommended for increased consumption by people in developed countries. Cole crops supplement staple foods of higher caloric value with protein, vitamins, minerals, and dietary fiber. While epidemiological studies have demonstrated the health benefits of cole crops, they do contain some antinutritional constituents.

The vegetable parts of the cole crops have a high water content, are low in lipids and carbohydrates, and as a consequence, have relatively low caloric value (Table 2). They are most notable as a source of soluble and insoluble fiber, calcium and potassium, vitamin C, folate, and carotenoids (b-carotene [beta-carotene] and lutein) when compared to other vegetables of similar water content. Although the protein level is low, cole crops do contain significant levels of the essential sulfur-containing amino acid methionine, but not cysteine.

Several compounds give cole crops their characteristic flavor, and affect health and nutrition (Table 3). Glucosinolates and their breakdown products are the best characterized of these compounds. Glucosinolates are a class of sulfur-containing glucosides of which about fif-

## GLUCOSINOLATE-DERIVED COMPOUNDS

Glucosinolate-derived compounds have also been implicated in plant defense against pathogens and vertebrate and invertebrate pests. While they may deter generalized predators and pathogens, certain pathogens and insects can detoxify these compounds, and they may in fact serve as an attractant. Further research is needed to clarify the complex and varied roles played by glucosinolate-derived compounds. If consumed in moderation, the beneficial effects of cole crops on health far outweigh deleterious effects.

teen occur in significant quantities in the Brassicaceae. Within a given species, only three or four glucosinolates may be present in high concentrations. Glucosinolates are found in all *Brassica* tissues, and are generally highest in seeds, intermediate in young vegetative tissues, and lowest in older vegetative tissues. Myrosinase metabolizes glucosinolates to various isothiocyanates. Normally stored apart from glucosinolates in myrosin cells, myrosinase only comes into contact with its substrate when cells are ruptured. The type of isothiocyanate formed depends on the composition of the precursor glucosinolates, the pH, and the presence of certain cofactors such as ferrous iron. Glucosinolates have little flavor; rather, the breakdown products are responsible for the characteristic flavors of the cole crops. In their most extreme form and concentration, isothiocyanates cause the pungency of horseradish. In the cole crops, these compounds in too high a concentration may impart a bitter or "spicy" flavor. The wild cole crop progenitor has fairly high glucosinolate concentrations, which have been reduced in the domesticated species.

Glucosinolate-derived compounds have both positive and negative nutritional effects. Isothiocyanates are goitergenic in animals and people if consumed in sufficient quantities. In brussels sprouts, degree of bitterness correlates with level of the isothiocyanate goitrin, so named because of past association with goiter.

On the positive side, epidemiological studies have demonstrated that a diet high in fruits and vegetables, and in *Brassica* vegetables in particular, limits the risk of certain cancers. Glucosinolates may prevent cancer by acting as metabolic detoxicants to facilitate alteration and excretion of cell carcinogens. Sulphoraphane, a sulphinyl-containing isothiocyanate, is a strong inducer of the phase II enzymes responsible for anticarcinogenic activities. While sulphoraphane is found in most cole crops,

sprouted broccoli seeds have the highest concentrations. This finding by Paul Talalay's group at John Hopkins University has stimulated the commercial production of broccoli sprouts.

Glucosinolate-derived indole compounds are inducers of liver and intestinal enzymes that reduced tumor formation in rats. Timing is critical, in that while these compounds were effective when ingested prior to the carcinogen, administration after introduction of the carcinogen increased carcinogenesis in rainbow trout.

Other compounds of nutritional importance are flavonoids and S-methylcystine sulfoxide. Broccoli contains relatively high levels of the anticarcinogenic flavonoids kaempferol and quercetin. Purple cabbage and other purple- or red-pigmented cole crops contain various anthocyanins. While anthocyanins in other crops

have shown anticarcinogenic properties, similar studies have not been carried out for cole crop anthocyanins. S-methylcystine sulfoxide is hydrolyzed by cystine lyase to methyl methanethiosulphinate, a compound that is similar to allyl thiosulphinate found in garlic. These compounds influence flavors, and are anticarcinogenic. Because of the similarities, and the health benefits found associated with these compounds in *Allium*, further study is warranted in the *Brassica*.

## History

**Original extent and domestication.** The wild progenitor of *Brassica* is found on the rocky Atlantic coasts of Europe (Bay of Biscay) and Britain. Researchers now believe that the free living *B. oleracea* populations found along the Mediterranean coast are feral and weedy escapes from cultivation. Related wild Mediterranean species (*B. cretica*, *B. insularis*, *B. montana*, and *B. ruprestris*) may have contributed genetically to the domesticated crops, al-

though molecular data does not support this hypothesis. Definitive archaeological evidence is lacking, but the crop was almost certainly a late domesticate compared to the primary domesticates of the Near East center such as emmer wheat, barley, pea, and lentil.

Different cole crops were likely domesticated in different places at different times, and multiple domestication within a type cannot be ruled out. More recent hybridizations among different types further complicate the picture. Leafy kales and nonheading cabbages were most likely the first domesticates, with some researchers hypothesizing that separate domestications occurred from Greece to Wales. "Stemkales" and headed and sprouting cabbages were described by Greek and Roman writers, although it is unclear whether these crops were the ancestors to the modern cabbage and broccoli. Domestication occurred prior to 1000 B.C.E., and possibly a millennia or more earlier. Broccoli and cauliflower are recent domesticates (possibly as old as 500 B.C.E.) from the eastern Mediterranean, and perhaps as localized as Cyprus and Sicily. The first clear description of broccoli and cauliflower was written about 1100 C.E. in Spain. Brussels sprouts were domesticated in northern Europe (some say Belgium) in about the fourteenth century. Early herbals depicted a kale with enlarged leaf axil buds, inferring that brussels sprouts were derived directly from kale. Kohlrabi may have been derived from marrowstem kale, or from a cross of marrowstem kale with cabbage. The origin of collards is closely associated with cabbage; whether collards are an ancestor or descendant of cabbage is unknown.

**Historical diffusion.** From Europe and the Mediterranean, cabbage and kale dispersed into Mesopotamia and Egypt. These crops later spread throughout the Old World along trade routes, eventually reaching China where distinctive kale and broccoli types were to compete with the *B. rapa* cabbages of East Asian origin. When trade with the New World began, all of the cole crops were taken to the Americas. In the tropics, cole crops were widely accepted, except for broccoli, which does not form heads under tropical conditions.

Broccoli and cauliflower diffused from the Mediterranean (cauliflower earlier than broccoli) to elsewhere in the Near East, northern Africa, and Europe. Cauliflower was mentioned in Turkey and Egypt in the sixteenth century and in England and France in the seventeenth century. Both broccoli and cauliflower were first described in the United States in 1806, but production did not flourish until the 1920s. The broccoli industry became established about 1923 when the D'Arrigo Brothers Company began growing broccoli in California and catering to the large Italian immigrant population on the East Coast. Interest in broccoli in central and northern Europe increased after the crop became popular in the United States, and worldwide, broccoli production is increasing.

## Procurement

**Agriculture and crop husbandry.** The majority of cole crop hectareage is found in the milder growing areas. The optimum growing season is determined by an interaction among latitude, altitude, and time of the year, as well as proximity to temperature-moderating oceans and lakes. In the United States, most of the cole crops for processing are produced at northern latitudes (New York, Wisconsin, Oregon, and Washington), the exception being California. The leading state for fresh market production is California, followed by New York, Georgia, Arizona, Texas, and Florida. Winter production in the United States of cole crops is done in Florida, Texas, and California. In the subtropics and tropics, cole crops are generally produced at higher altitudes. Commercial cauliflower production is restricted to the maritime climates of the United States because of its sensitivity to heat during curd formation.

For commercial production, the crops are generally grown in monoculture in 50–75 cm rows with within row spacing of 15–30 cm. Crops may be direct seeded or transplanted. Direct seeding is cheaper, but transplanting generally produces a more even stand with more uniform maturity. Cole crops require about 2.5 cm per week of moisture applied regularly throughout the season. In most production areas, natural precipitation is supplemented with irrigation.

Optimum soil pH is 5.5–6.5. Liming low pH fields improves micronutrient uptake and reduces incidence of club root. Plentiful amounts of nitrogen, potassium, and phosphorus are required for optimum plant growth. Nitrogen may be applied as a split application. Cole crops require adequate quantities of boron, calcium, and magnesium.

**Harvesting and packing.** Cabbage may be hand- or machine-harvested. Generally, heads intended for fresh market are hand-harvested, while those destined for storage or sauerkraut are mechanically harvested.

Broccoli and cauliflower are entirely hand-harvested. The greatest impediments to automating harvest are lack of cultivars with suitable plant architecture and a nonuniform maturity across a field. Even with F<sub>1</sub> hybrids and transplants, microenvironment differences will cause differential maturation in different parts of the field. Growers typically harvest two or three times at several-day intervals to maximize harvest of heads at optimum maturity. Attempts to develop a selective harvester for these crops have not been successful to date.

Brussels sprouts may be hand- or partially machine-harvested. The lower buds on the plant mature before those on the upper portion of the stem. Sprouts are harvested by hand at three or four-week intervals during the growing season by breaking the petioles of the lower leaves, then snapping the mature sprouts. If a single harvest is desired, the terminal growing point is removed

## SAUERKRAUT

Fermenting cabbage to make sauerkraut is an ancient practice. The process is simple, and facilitated long-term storage of the crop. Sauerkraut is made by salting shredded cabbage and placing the mixture in an anaerobic container to ferment. Salt draws moisture from the cabbage leaves to produce a brine solution (ideally 2.25 percent). The brine inhibits growth of most microorganisms but allows certain anaerobic bacteria to propagate. *Leuconostoc mesenteroides* initiates the process, while others (primarily *Lactobacillus*, *Streptococcus*, and *Pediococcus* spp.) continue fermentation. There are a number of conditions that need to be met, or a poor quality product will result. Salt must be evenly distributed, otherwise soft or pink kraut will form. Temperature will affect the composition of the microbial population, which in turn determines the pH and mix of flavor components. Temperatures below 18°C will produce sauerkraut with the best flavor, highest acidity, and ascorbic acid. Nonanaerobic conditions will allow yeast and molds to grow, which will impart undesirable flavors and odors, and will cause spoilage. Sauerkraut is preserved by canning. Sauerkraut is typically consumed with meat or poultry, but may also be used in salads. Sauerkraut juice may be blended with other vegetable or fruit juices to produce a novel and pleasing product.

Today, many people mainly associate sauerkraut with a condiment served on their hotdog bun at a baseball game. In northern Europe during the winter and on Western sailing ships, sauerkraut was an essential staple. The pickling process preserved about one-third of the vitamin C contained in the cabbage leaves, and provided a source of this essential vitamin at times when it was unavailable from other foods. For example, Captain Cook carried sauerkraut on his voyages of exploration as a preventative for scurvy. Fermented products, such as kimchi in Korea, which is made with Chinese cabbage (*B. rapa*) or Daikon radish (*Raphanus sativus*) serve a similar purpose in the temperate Asian world.

when sufficient height and lower bud development has been achieved. Upper buds will then catch up with lower buds in growth, resulting in near-uniform-sized sprouts along the stem. Plants are then cut in the field; the leaves are removed and sprouts are sheared from the stalk using a sprout cutter.

In large-scale operations, broccoli, cauliflower, and cabbage harvested for fresh market are packed in the field.

After broccoli heads are cut from the plant, leaves are removed and a mechanical cutting and banding machine is used to trim the stems to 15–20 cm in length. Two to four heads are bundled using rubber bands or a twist-tie. The prepared heads are then packed in a box and quickly cooled to 32°F (0°C) using slurry ice (40% ice and 60 percent water), which is hosed directly into the box. Cauliflower heads are harvested for fresh market when they grow to 15–20 cm in diameter. They are trimmed of most leaves (leaving a few basal leaves to protect the heads from damage), sorted to uniform size (typically six, twelve, or twenty-four heads per crate), and packed into crates or cartons. Individual heads may be wrapped with perforated film. Cauliflower is cooled to 32–36°F (0–2°C) for shipping and storage. Cabbage heads are harvested when firm and 1–1.5 kg in weight. Wrapper leaves are trimmed and heads are sorted and packed into crates or cartons and cooled to 32–36°F (0–2°C). Vacuum cooling, rather than slurry ice, is used to cool cabbage and cauliflower. Hand-harvested brussels sprouts are carried from the field in containers, washed and sorted for size and firmness, and quickly cooled (usually vacuum cooling) to 32°F (0°C). Sprouts are packaged in cellophane bags or baskets.

**Storage and Processing.** All of the cole crops are stored at near freezing, typically 30–36°F (–1–2°C) and at high (90–100 percent) relative humidity. Cabbage can be stored up to four months under ambient conditions and up to six months in modified atmosphere storage. Broccoli can be stored for only one to two weeks, cauliflower for two to three weeks and brussels sprouts for three to four weeks under optimal conditions in normal atmosphere storage.

The cole crops may be preserved by canning, freezing, pickling, dehydration, or fermentation. Broccoli, cauliflower, kale, collards, and brussels sprouts are usually processed by freezing. Cabbage may be dehydrated, or fermented to produce sauerkraut. Brussels sprouts, cabbage, and cauliflower may also be pickled. Kale and collards may be canned.

Seeds of the cole crops, especially broccoli, are consumed as sprouts. Extracts of cabbage-derived anthocyanins are being used commercially as red food colorants.

**CACTUS.** Cacti are succulent perennials that are native to arid and semi-arid regions and are cultivated extensively, except where freezes regularly occur. The land area devoted to cactus cultivation in 2001 was about 1.8 million hectares (4.4 million acres), mostly for fodder, and over half of which was in northern Africa and northeastern Brazil. Cacti are also cultivated in over twenty countries for their fruits, which commercially fall into three categories: cactus pears, which are the fruits of the prickly pear *Opuntia ficus-indica* and certain other cacti with flat stems (cladodes), and represent over 90% of the cactus fruits sold; pitahayas, which are the fruits of vine cacti in the genera *Hylocereus* and *Selenicereus*; and pitayas, which are the fruits of columnar cacti. Young cladodes are consumed as a vegetable (*nopalitos*), particularly in Mexico. Nearly all cacti employ a photosynthetic pathway known as Crassulacean acid metabolism (CAM), in which the stomates (shoot pores that allow CO<sub>2</sub> entry) open primarily at night, when temperatures are lower and water loss is lower than for the overwhelming majority of plants, whose stomates open during the daytime. The best known edible CAM plant is pineapple, which is cultivated on about half as much area as cacti. Because of their lower water loss, cacti and other CAM plants thrive in dry regions (and also require little or no irrigation when cultivated in other regions).

#### History

Although evidence for cacti in human diets goes back more than 8,000 years in present-day Mexico, worldwide consumption has developed only in the last few hundred years. Cacti were introduced into Europe in 1495 from the second trip of Christopher Columbus to the New World. *Opuntia ficus-indica* spread across the Mediterranean region in the sixteenth century, where it readily grew under the local semi-arid conditions. Also in the sixteenth century, Spaniards introduced *Hylocereus undatus* into the Philippines, whence it spread throughout southeast Asia. In the nineteenth century, it became es-

established in Viet Nam and is now extensively cultivated in the Mekong Delta, where its tasty fruit with red peel and white pulp is called “dragon fruit.” Also in the nineteenth century, the columnar *Stenocereus queretaroensis* was domesticated in Jalisco, Mexico. None of these species received much agronomic attention until the end of the twentieth century, and even then the money for research and development was meager. Both fruit crops and young cladodes used as vegetables require much hand labor. Although machines have been developed to remove the irritating small spines (termed “glochids”) from cactus pears, many improvements in their cultivation await future research.

### Fruits

Fruits of many cacti are edible. Indeed, the Seri Indians of the southwestern United States and northwestern Mexico consumed fruits from over twenty species, including those of the saguaro cactus (*Carnegiea gigantea*), used by various Native Americans for fruits and wine. Fruits collected from the wild influenced the species selected for domestication. Such selections involved various species of *Opuntia* in Mexico, eventually leading to the presently planted cultivars.

**Cactus pear.** The fruits of *Opuntia ficus-indica* and a few other prickly pears are harvested in the summer from plants that are one to three meters tall. Harvest can be delayed by removing the early flowers, as is commonly done in Sicily, leading to a second harvest in the autumn that is more valuable per fruit due to lessened competition from other species. One-year-old cladodes can bear five to fifteen fruits each; terminal cladodes with fewer fruits tend to bear larger ones (over 150 g each), which command higher prices. After harvesting, the fruits must have the glochids removed mechanically, after which they are often packaged by color and weight. Fruits with red pulp are prized in the United States and certain European countries, whereas greenish pulp for mature fruits is generally preferred in Mexico. Although sold in supermarkets worldwide, fruits are also sold by street vendors, who slice the peel and provide the exposed pulp directly to the consumer. The relatively large seeds are a detriment to fruit consumption by many, but the seeds are harmless and readily swallowed by aficionados.

The country with the greatest land area devoted to cactus pear cultivation is Mexico (Table 1). Annual production can be over fifteen tons fresh weight per hectare under intensive management. In Mexico, Sicily, Israel, and the United States, most production is from commercial plantations, whereas in other Latin American countries and in northern Africa, a large amount of the fruit is collected from hedges and other informal plantings.

**Pitabayas and pitayas.** The most widely cultivated pitahaya is *Hylocereus undatus*, which in 2001 was cultivated on about 12,000 hectares in many countries, including Viet Nam, Taiwan, the Philippines, Mexico, Guatemala,

TABLE 1

#### Land areas and harvests for fruit production by *Opuntia ficus-indica* and closely related species in 2001

Country	Area (hectares)	Annual harvest (tons fresh weight)
Argentina	900	8,000
Bolivia	1,300	3,500
Chile	1,200	9,000
Israel	400	7,000
Italy	7,500	80,000
Mexico	70,000	400,000
Northern Africa (Algeria, Morocco, Tunisia)	~20,000	—
South Africa	200	1,500
United States	200	3,600

Peru, Colombia, and Israel. It is a vine that is trained to grow on posts, trellises, or arbors. Its relatively large fruits (generally 250 to 500 g) are harvested after the peel, which has no spines or glochids, turns red. The pulp is

Vendor selling cactus pads in Guanajuato, Mexico. © DANNY LEHMAN/CORBIS.

whitish with small black seeds. Other species of *Hylocereus* and *Selenicereus megalanthus* have peels and pulps of various colors, leading to a wide choice of tasty and visually appealing fruits.

Although their cultivation is expanding rapidly, in 2001 pitayas were harvested on only about 3,000 hectares worldwide, mostly in Mexico, from species like *Cereus peruvianus*, and especially *Stenocereus queretaroensis* and other *Stenocereus* species. Fruits grow along the main stem and branches about two to six meters above the ground, requiring a pole with a basket-like attachment for harvest of individual fruits. Fruits of *Stenocereus queretaroensis* have an attractive and tasty dark red or purple pulp with small seeds (like those in kiwis) that are easily swallowed. However, the fruits tend to split within two or three days after harvest, requiring rapid local consumption.

### Vegetables

Tender young cladodes about 10 to 15 cm long of *Opuntia ficus-indica*, *Opuntia robusta*, and a few related species are used in Mexico as *nopalitos*. About 6,000 hectares were cultivated for this purpose in 2001, and *nopalitos* are also prepared from plants in the wild or growing around houses, or as hedges. The raised portions of the stem containing spines and glochids are readily removed with a knife or by machine. The cladodes are then generally sliced or diced and blanched in a weak saline solution for a few minutes to remove excess mucilage. After draining, the material can be cooked, yielding a vegetable with a taste not unlike string beans or okra. Because of their high fructose and mucilage content, *nopalitos* are highly recommended for people with type II diabetes. Often the blanched material is pickled and used as a relish or in salads. More than thirty companies sold pickled *nopalitos* in Mexico in 2001, and this product is in supermarkets worldwide.

### Other Uses

Other uses of cacti range from candy made from the stems of barrel cacti that have been infused with a sugar solution to peyote from dried stems of *Lophophora williamsii*, used by Native Americans for ceremonial purposes. Flowers have been used for medicinal purposes and to make perfume. The seeds of cacti such as *Opuntia ficus-indica* have been dried, ground, and then used as a flavoring paste for cooking. Carminic acid, an important red dye for food coloring, can be extracted from dried cochineal insects that feed on *Opuntia ficus-indica*. Although most cactus pears are consumed fresh, sorbets and marmalades are also prepared from the fruits. The strained pulp of fresh fruits is used as a fruit drink or fermented to make wine. Fruits of cactus pears are also partially dried and sold in brick-sized blocks in Mexico. More than thirty brands of dried and powdered cladodes are sold in Mexico as a dietary supplement. The range of edible products from cacti is indeed great and their use is steadily increasing, as more people become willing to try

new and natural foods, and growers search for crops that do not need irrigation.

**CAJUN CUISINE.** See **United States**.

**CAKE AND PANCAKE.** The cake, as we now understand it in Anglo-American cookery, is the product of western European culture, with few parallels in non-European cookeries. It is commonly expressed in French by the word *gâteau*, a term without specific meaning (*gâteau de pomme* is both an apple cake and a molded apple jelly) and whose origin remains undetermined. Nevertheless, since the nineteenth century, the culture of the cake has spread to many parts of the world as the result of colonialism and the internationalization of French, English, and more recently of American cookery.

In Latin America, for example, American-type layer cakes are called *queques*, but the more traditional Spanish term *pastel* is often employed for birthday cakes of similar shape and structural arrangement. The use of conflicting terminologies for cakes, and the multitudes of types of foods defined as cakes, make it difficult to create a standard logic and a simple definition. No scholarly undertaking has thus far tackled the cake to create a unifying thesis about its diverse evolutionary forms. This would require a detailed analysis of the huge vocabularies for cake and cakelike pastries that exist in many European languages both ancient and modern. The discussion here will focus on the cake in relation to American cookery.

The concept itself is quite basic: cake is bread, if bread is defined as something baked from flour or meal, as in Welsh oatcake. However, this basic idea has evolved in English to cover a number of preparations also generally categorized as sweet and normally considered dessert or special occasion foods. While nearly all types of modern cakes are thought to have evolved out of some form of enriched bread, that course of evolution is highly varied from culture to culture and encompasses a great many regionalized forms and colloquial names. Both the

word *cake* and the preparations associated with it have experienced sometimes separate and convoluted histories.

The word is generally assumed to have entered English via Old Norse *kaka*, although this line of derivation is doubtful, since the Norse word itself was assimilated from Vulgar Latin, for a similar root may be observed in such terms as the Dutch *coeke* and *koek*. *Koekje*, the diminutive of *koek*, was corrupted in colonial American English as *cookie* (literally a “little cake”), yet it preserves the essential concept that the cake is flat and baked, regardless of size—an important point. Since a similar term *kuoche* appears in medieval German, also for a type of enriched bread flat in shape, it is quite probable that cake entered modern English as a Latin loan word via ancient British or Anglo-Saxon rather than Old Norse, although literary documentation does not surface until the 1300s. Neither Billy (1993) nor Lambert (1997) has ascertained Celtic roots for the term; thus a Latin origin must be presumed.

Whatever the route of assimilation, the root meaning of cake is quite clear, for it is expressed in the Latin verb *coquere*, to cook or prepare food in the limited sense of baking or exposing it to heat it in some way. German and the other languages that assimilated this verb-concept also extended it to mean something baked that is both flat and made with or covered with ingredients that differentiate it from common flat bread, hence terms like *Kuchen*, *Fladen*, *Wäbe*, and *Zelten* in German-speaking Europe. *Torte*, a word derived from Latin *tortum*, moved into German and other northern European languages (such as Polish) via French or Italian during the Renaissance and entered English as *tart*. The fruit tart of Renaissance England evolved into the colloquial fruit pie of colonial America and there departed from its ancient flat cake ancestry, which may be said to linger on only in the shape of the bottom crust.

However, very primitive types of cake do survive in the form of the Alsatian *quiche* (derived from German *Kuchen*)—where the rim of the cake dough is turned up to allow for a deeper covering or filling (common cheese-cake also belongs to this category). Another type is like the so-called *galette bretonnaise* (Breton flat cake), which is round, flat, sweet in taste, and enriched with butter. It is baked on a griddle or bake stone and thus shares a common lineage with the bannock and *scon* of the insular Celts. A Mediterranean counterpart would be the *karydopita nistisimi* (Lenten walnut cake) of Greece eaten with syrup. The sweet johnnycake of colonial America is a New World extension of this primitive flat cake concept. The hoecake (a flat bread baked on a shovel) and the ash-cake (a flat bread baked under hot coals) are both variants of this basic type.

It is also clearly evident from surviving written evidence that medieval cakes were not necessarily sweet, for they could include such ingredients as cheese and herbs, a batter of cheese and eggs, a few slices of sausage,

Cake stand and glass bell cover manufactured by Whitehall & Tatum, Millville, New Jersey, circa 1840. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

or even a mixture of fruit and vegetables. In their original dietary contexts, such cakes were not viewed as everyday fare, but were reserved for special occasions such as time of harvest, a village fair, a saint's day, or some similar event. The most festive cakes were those enriched with fat and fruit, or sweetened with fruit and honey, and out of that tradition of elaborately flavored bread evolved most of the rich cakes we know today. French pastry cooks generally divide cakes into eight categories based on the type of doughs employed, but these are merely terms of convenience. There are only four structural families.

### The Galette or Short Bread

The galette or short bread is the type described above in connection with *galette bretonnaise* and American sweet johnnycake. The unifying features include an enriched, stiff unleavened dough—which may be molded or flattened by hand or with a rolling implement—a round shape, and a brittle texture once baked. The cake may be further ornamented by impressing images or patterns into the surface. These cakes rely for their tenderness or soft texture on a combination of fat (usually butter) and specially selected flours, such as soft wheat flour or a mixture of barley flour and wheat, or even to some extent on breaking the dough by beating it. They are now commonly categorized as pastries, especially since this type of dough is now employed to make cookies, but historically, such short doughs were treated as cakes as long as they conformed to a flattened shape. When the short breads are stacked and interfilled with rich ingredients, they are almost always referred to as *tortes* or *gâteaux*. An example of the former would be the linzer torte of Austria, while the French *gâteau mille-feuille* would be an

A yeast-raised Gugelhopf cake with raisins, as depicted in a nineteenth-century German wood engraving. ROUGHWOOD COLLECTION.

example of the latter. This French cake is perhaps the most fragile of all, since it is constructed of layers of round sheets of puff pastry interfilled with various sorts of cream and jam.

### Bread Cakes or Loaf Cakes

These may be further divided into sweet and savory types. An example of the latter would be the common Italian *focaccia* covered with herbs, cheese, and sliced tomatoes. An example of the sweet type would be the early American Moravian sugar cake, which is essentially a sweetened yeast-raised dough into which is inserted a mixture of brown sugar, cinnamon, and butter. This is accomplished by making holes in the surface of the dough and pressing the mixture in with the index finger. The common thread is that these cakes are yeast-raised and therefore most like bread in texture. Furthermore, they were meant to be eaten out of hand like a piece of bread. Many sweetened festive breads of the Mediterranean preserve this old form, especially in the elaborate preparations of Greek *Vasilopita* (St. Basil's cake) for the New Year and the numerous traditional Cypriot breadlike cakes ornamented with dried fruit, almonds, and brightly colored comfits.

The yeast-raised *Gugelhopf* or *Napfkuchen* of southern Germany and Austria are further extensions of this basic idea, with the additional refinement that the bread is baked in a form so that it acquires an impressive ornamental shape. Rather than sticking fruit into the surface, it is chopped and worked into the dough itself. The Worcester loaf cake of New England, which was similarly baked in a shaped cake pan, provided early Americans with an equivalent example. Its vernacular name, however, indicates that originally (in the 1600s) it was

baked round to resemble a loaf of bread, and like bread, it was not made too sweet since it was served with jam or preserves on ceremonial occasions such as funerals. This type of yeast-raised cake achieved its most monumental and most vertical expression during the Renaissance and Baroque periods in such phallic shaped cakes as the Russian Easter cake and the Polish baba.

### Baked Pottages or Plum Pudding Cakes

Plum pudding cake was once found in many parts of medieval Europe, but quickly disappeared during the Renaissance in favor of lighter and sweeter preparations. Since the plum cake was associated with traditional fall butchering and Christmas feasting in England (and may be traced to pagan times), it has lingered on in British cookery to this day. It was also brought to colonial North America, where it continues as a feature of Christmas fare under the name of fruitcake. Fruitcake is especially popular in the American South.

In order to understand the origin of this cake, we must start with something similar to mincemeat thickened with meal, cracked wheat, or flour, to which is added a variety of rich ingredients. These would include blood from butchering (hence the term black cake), suet, butter, dried fruits, honey, and a variety of spices. This could be served freshly made as a festive pottage, or baked thick in a pan or shallow crock and later turned out like a wheel of cheese. The use of pottery for such purposes is attested to by Michael Hero, who illustrated something similar called *Scherbenbrodt* (crock bread) in his *Schachtaffeln der Gesuntheit* (Strasbourg, 1533).

At this point, the baked mass becomes a cake due to its round, flattened shape and solid texture, and black cake

it is indeed. Furthermore, it can be sliced and eaten with the fingers; thus it migrates from the medieval pottage course to an *entremet* for the final course, when various sweets and delicate foods are served. From here, the cake undergoes rapid metamorphosis, with increasingly more eggs, sugar, spices, candied fruits, and other ingredients associated with luxury, leaving the homey pottage altogether to evolve along a separate line into plum pudding. One unifying feature, however, is the dark color that came initially from blood, but which is later derived from molasses or brown sugar. Both plum pudding and fruitcake retain this visual allusion to their ancient association with butchering. And to some extent, both have retained their medieval role as visual centerpieces during the course of the meal.

The festive nature of this type of cake, which eventually comes to rely on beaten eggs for its lightness, is preserved in names like rich bride cake, Twelfth Night cake, and Christmas plum cake. More refined (less dark) versions developed into tea cakes, such as Dundee cake and Cumberland fruit cake. The latter preparation has many counterparts in Victorian cookery books. Both the bride and Twelfth Night cakes were similarly ornamented with elaborate icings, but the bride or wedding cake has since evolved into something quite different, having crossed over the line into the next category of cake discussed below.

The traditional bride cake made with fruit as described here probably fell out of fashion due to its dense weight, since it could not be stacked to a great height without crushing the layers underneath. Furthermore, there is considerable work involved in icing it, since it must be coated with a hard layer of marzipan to keep moisture from seeping out into the highly ornamented royal icing encasing the whole creation. Such seepage would stain the work or dissolve it altogether. This telling detail is evident in the fact that most commercial American fruitcakes are no longer sold iced, since this requires a level of competence now dispensed with in large-batch operations.

### Pancakes and Batter Cakes Baked in Pans

This takes us into a realm of research that on one level is refreshingly simple, yet on another, perplexing and ambiguous. Let us deal with the ambiguities first. Most of the cakes in the category of pancakes and batter cakes cooked in pans are referred to in French as *gâteaux*, since they are now of a large and impressive sort. Unfortunately, the origins of the word *gâteau* are obscure, although the *Viandier* of Taillevent (1380s) mentions something called a *gaitellet*, which has been glossed as a little cake. This would imply that there were cakes larger than a *gaitellet* and known by another closely related name (*gaitelle*). If this has a Gaulish root (which is possible), it may derive from a cognate of the Latin *catinus*, a deep dish or bowl, or more specifically from *catillus*, the diminutive for a dish or plate (here again the inference

Stacked tube pans for *gâteau breton*. Made by E. Dehillerin, Paris, ca. 1912. White metal. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

is something flat in shape). This is, of course, quite speculative, but leaves one fact beyond doubt: the cake in question is created from batter, from something liquid that is first beaten light.

We are on firmer ground with the 1398 observation of John of Trevisia who saw in England a cake “tornynd and wende” at the fire. He even said that it was called a cake and his comment is in fact considered one of the earliest documented uses of the word. What he observed was the preparation of the once popular spit cake (*Spiesskuchen*) much depicted in the paintings of Bruegel and other north German artists. This is created by dripping well-beaten batter onto a hot spit as it turns before the fire, thus spinning out a series of flat irregular cakes in accordion fashion. This was served set on end as a type of wedding cake, one of the few ways in which medieval cooks could raise a batter cake to great heights. Verticality is a feature of many cakes of a highly festive nature, and this cake is still made today by professional bakeries in France, Belgium, Holland, and Germany.

The spit cake is an anomaly in its unusual method of baking. Most batter cakes were created in a much more straightforward manner: down hearth in a bake kettle (Dutch oven). However, this takes us into yet another region of ambiguity concerning the origin of the cake, since we must now confront the pan and the ways in which it dictated the evolution of all cakes composed of batter. It would seem logical to presume that the *pan-* in “pancake” refers to Vulgar Latin *panna*, which is normally glossed as a shallow pan or vessel. But all things did not flow from Rome. Thus we might also look to

words such as the Belgic and Treverian Gaulish *panna* (a likely source for the Vulgar Latin in any case) for a more basic explanation and a richer understanding of the batter cake.

The meaning of *panna* is well attested to by its survival in Westphalian German under the name *Pannas*, a festive pot pudding made during the butchering season that is solidified in a pan, then sliced and fried in little cakes. One of the original Belgic meanings of *panna* was a cauldron or kettle (in which the pudding was boiled), but more abstractly a cooking implement or ceramic form of varying depth. These alternative meanings survive in German as *Pfannkuchen* or *Pfannzelten* (south German), cakes that are hearth-baked in a kettle—a concept that survives in the form of the Dutch oven and colonial American spider corn cake.

The thinnest sorts of batter cakes are those most like the pancakes and crepes made from milk, flour, and egg and served today as breakfast foods. They evolved out of omelets to which flour, fat, and other ingredients were added in ever-increasing amounts. The next immediate stage would be cakes resembling the Italian *frittata*, then soufflés (cakes that deflate), and finally batters that actually contain enough structural material to bake firm and retain their shape. Such pan-baked delicacies were known even in the early Middle Ages, for in his *De honesta voluptate et valetudine* (1465) Platina published a recipe for a Byzantine *artolaganos* (pan or layer cake) prepared with eggs, sugar, cheese, and finely ground millet. His recipe came from Milanese chef Martino di Rossi under the name *migliaccio* (millet cake), proof that delicate, batter-based cakes were already a feature of Italian court cookery by that time.

At this point, the pancake moves further along two separate lines of evolution. Since thickness and lightness were increasingly sought after, the pan itself became taller and taller to contain the new heights being achieved. More closely controlled results could be expected in an oven, so batter cake cookery was soon transferred to the bake oven. It is important to remember that Rossi's *migliaccio* was baked in a kettle down hearth, as most peasant variants of this type of cake continued to be baked well into the nineteenth century. However, cakes with heavy ingredients, like the *migliaccio*, soon evolved into delicate pound cakes once freed of the smoky, drafty atmosphere of the hearth, while batters with reduced fat and more beaten egg whites followed the *frittata* to its ultimate conclusion in Savoy and sponge cakes. Denser batters were baked in pans—at first round, like hearth implements, then square; finally, during the late Renaissance we witness the cake evolving into the multitudes of shapes depicted in many French cookery books of the period.

The replacement of flour with highly refined commercial starches and the replacement of eggs with chemical leavenings allowed the development of lighter and lighter cakes during the nineteenth century. The angel

food cake invented in the 1870s by Linus Dexter of Vineland, New Jersey, was the product of just such a technological shift. Likewise, American cooks began to stack one cake upon the other to create the thick layer cake, a response no doubt to a similar evolution in the wedding cake, which soared to great heights once freed of its old fruit cake foundation. The opposite may be said for chocolate cakes, which now vie for density and richness. They may have replaced the sinfully greasy baked pot-tages of the Middle Ages (although still dark in color), and they may be relegated to dessert carts in the scheme of many modern restaurants, yet fine cakes still command a place of high esteem by virtue of their sheer voluptuousness. They have become the alter ego of a society obsessed with the ills of overabundance.

William Woys Weaver

**CALCIUM.** Calcium (Ca<sup>2</sup>) is a silver-white metallic element of the alkaline-earth group. Ninety-nine percent of calcium in the human body is in bone and teeth. The remaining one percent is in blood and body fluids. In addition to its role in maintaining strength of bone and teeth, calcium is involved in nerve cell function, control of muscle tone, and blood clot formation. Calcium is also necessary in order for many important proteins to properly perform critical metabolic functions throughout the body.

## Functions

**Cells.** Calcium concentrations in the fluids outside cells are much larger than calcium concentrations inside cells (the cytosol). Unequal calcium concentrations in the extracellular fluid and cytosol are required for cells to carry out many crucial functions. For example, when a hormone in the blood binds to a receptor on the cell, calcium pours into the cytosol from extracellular fluid. This change in the amount of calcium in the cytosol signals the cell to perform some critical function. The critical function that is triggered depends on the type of cell. (In muscle cells, for example, a nerve signal triggers the release of calcium into the cytosol, allowing muscle contraction to occur.) After the critical function is performed, calcium is rapidly pumped out of the cell, and the calcium concentration in the cytosol returns to the normal (low) level.

**Structural.** In addition to cellular functions, calcium's more familiar role is a structural one—as a component of bones and teeth. Blood calcium levels are maintained strictly even if calcium has to be taken from bone. Bone mineral (hydroxyapatite) is made up primarily of calcium, phosphate, and carbonate. Bone constantly changes during growth and throughout adulthood. Changes in bone occur through balancing activities of bone-destroying cells (osteoclasts) and bone-forming cells (osteoblasts), which act together to remove and replace bone, respectively. During growth, bone formation generally exceeds destruction, yielding net bone-mass gain in the whole skeleton.

Bone-mass accumulation continues until peak bone mass is achieved, generally during the third decade of life. The age at which peak bone mass is reached varies by gender and differs by skeletal site. Males achieve peak bone mass later than females and gain more bone during puberty than females, resulting in larger bones. Although peak bone mass at all skeletal sites is generally reached by age thirty, bone accumulation is nearly complete by age twenty in the lumbar spine and in portions of the hip for both males and females. Genetic, environmental (for example, physical activity or mechanical “loading” of the skeleton), hormonal, and nutritional factors interact to influence peak bone-mass levels. Failure of an individual to reach the maximum peak bone mass permitted by his or her genetic makeup can be related to low calcium intake or a sedentary lifestyle without adequate physical activity. Parathyroid dysfunction, genetic or nutritional skeletal disorders, or medication use may affect peak bone-mass accumulation and overall bone health adversely. Smoking and excessive alcohol consumption also are likely to be detrimental to skeletal health.

After an individual reaches peak bone mass, net bone gain in the whole skeleton generally does not occur. Age-related bone loss occurs in both genders, but the rate of bone loss increases with estrogen loss at menopause in females. Age-related bone loss is caused by increased osteoclast (bone-destroying) activity compared to osteo-

blast (bone-building) activity. Physical activity during adulthood, combined with adequate overall nutrition and calcium intake, can help to maintain bone strength.

## Metabolism

**Absorption.** Calcium absorption across the intestinal wall into the blood occurs by different mechanisms. Two major mechanisms include passive diffusion and active transport. Vitamin D is required for the active transport mechanism but not for the passive diffusion mechanism. The percent of calcium that is absorbed into blood generally decreases with higher calcium intakes; however, the total amount of calcium absorbed is usually greater with higher calcium intakes. The percent of calcium absorbed into blood is highest in infants, spikes again at the start of puberty, then gradually declines with age. The percent of calcium absorbed into blood also increases during the last two trimesters of pregnancy.

**Homeostasis.** The body keeps tight control (homeostasis) of blood calcium concentration by continuously changing various factors. When blood calcium concentration falls below normal, the parathyroid gland releases parathyroid hormone (PTH). PTH stimulates increased removal of phosphate into urine by the kidneys. This increased phosphate removal triggers the kidneys to keep calcium in the blood rather than excrete it in the urine. PTH also stimulates osteoclasts to remove calcium from bone in order to help restore normal blood calcium concentration. Finally, PTH is involved in making certain that enough vitamin D is present in the intestine to allow for increased calcium absorption from the gut into the blood. PTH decreases to normal once calcium homeostasis is reached. Another hormone, calcitonin, is responsible for stopping bone breakdown by osteoclasts when blood calcium concentration is above normal. Thus, the hormones PTH and calcitonin work together to keep blood calcium concentration within a very narrow range.

## Dietary Requirements

**Bioavailability.** Both dairy products and most dietary supplements provide adequate amounts of calcium. Calcium is present in smaller amounts in grains, fruits, and vegetables. Because grains are eaten in high amounts, however, they are an important source of calcium. Other calcium-rich foods include bok choy (Chinese cabbage), kale, cabbage, and broccoli. Calcium from some foods containing high levels of oxalic acid (spinach, sweet potatoes, rhubarb, beans) or phytic acid (unleavened bread, nuts and grains, seeds, raw beans) is absorbed poorly due to formation of insoluble calcium salts. The ability to enhance dietary calcium intake by consuming calcium-fortified food sources is increasingly common.

Although high protein intake temporarily increases urinary calcium excretion, there is no evidence to indicate that calcium intake recommendations should be

adjusted according to protein intake. Although caffeine has a slightly negative impact on calcium retention, the modest calcium loss can be offset by a similarly modest increase in calcium intake. High salt (sodium chloride) intake usually results in increased urinary calcium loss because excretion of sodium and calcium at the kidney are linked. High salt intake triggers increased urinary sodium loss and, therefore, increased urinary calcium excretion. However, as with protein and caffeine, there is no evidence to indicate that calcium intake recommendations should be adjusted according to salt intake.

**Dietary requirements and bone mass.** Because circulating calcium levels are so strictly controlled, blood calcium concentration is a poor indicator of calcium status. Chronic inadequate calcium intakes or poor intestinal absorption leads to reduced bone mass as PTH acts to maintain homeostatic blood calcium at the expense of skeletal strength. Bone mineral content (BMC) and bone mineral density (BMD) are common measures of bone strength and fracture risk. BMC is measured in grams, the amount of bone mineral at the selected site (for example, whole skeleton, lumbar spine, hip, forearm) and BMD ( $\text{g}/\text{cm}^2$ ) are calculated as BMC divided by bone area in the region of interest. An adult is defined as osteoporotic by the World Health Organization if his or her BMD is more than 2.5 standard deviations below gender-specific normal young adult BMD. Osteoporosis and related spine, hip, and wrist fractures are major public health concerns.

Recommended daily calcium intakes (measured in milligrams) increase from infancy through adolescence. The rate of calcium accretion relative to body size is greatest during infancy. Infants accrete approximately 140 mg of calcium per day during the first year of life. This need for calcium during the first year of life is reflected in the amount of milk consumed by human milk-fed infants. Although evidence indicates that feeding of formula results in greater bone mineral accretion than human milk feeding during the first year of life, there is no indication that this effect is beneficial either short- or long-term.

Calcium accretion continues in childhood, and maximal accretion occurs during puberty. Children of ages one to eight years accrete 60 to 200 mg of calcium per day. Peak calcium accretion occurs during puberty for both males (mean age 14.5 years) and females (mean age 12 years). Accordingly, calcium intake requirements are highest during adolescence.

Calcium retention and bone turnover decline after menarche in females, but the amount of calcium women need does not change because the percentage of calcium absorbed into the blood decreases. In males, bone mineral accretion occurs until mean age 17.5 years. Evidence from clinical trials indicates that calcium supplementation in children can increase BMD, but the effect occurs primarily among populations who usually have low calcium intake, is not apparent at all skeletal sites, and prob-

ably does not persist when supplementation is stopped. Apparently the benefit is short-term only.

Dietary calcium requirements decline for both males and females once adulthood is reached and remain constant throughout the reproductive years. Intestinal calcium absorption, however, also decreases with age. At the end of the reproductive years (approximately age fifty), bone-mass loss occurs in both males and females. Bone-mass loss is particularly pronounced in females during the first few years following menopause. The bone loss that occurs with the loss of estrogen at menopause cannot be reversed simply through increased calcium intake. Reductions in age-related bone loss through calcium supplementation have been demonstrated in postmenopausal women, but the effects vary by skeletal site, usual calcium intake, and postmenopausal age. Because of the reduction in intestinal calcium absorption with age in all individuals and the potential of increased calcium intake to offset bone loss due to estrogen depletion, increasing the amount of calcium in one's diet is recommended for all individuals over fifty years of age.

Maternal calcium requirements increase during the third trimester of pregnancy in accordance with fetal growth needs and to prepare for lactation, and the mother's intestinal calcium absorption efficiency increases in order to meet her increased need for calcium. If this need for more calcium is not met, the mother's skeleton will be depleted to meet the calcium demands of the fetus. Furthermore, calcium loss from the mother's skeleton occurs during lactation and cannot be prevented by calcium supplementation. However, evidence indicates that maternal bone density is recovered to pre-lactation levels within approximately six months after the recurrence of menses.

**Toxicity.** Calcium toxicity is uncommon but can occur if too much calcium is taken in through dietary supplements. In susceptible individuals, excess calcium intake can lead to the formation of kidney stones (renal calcium deposits); however, dietary calcium is not a common cause of kidney stones. Hypercalcemia from ingestion of large quantities of calcium supplements is rare but the resulting kidney problems and ramifications to cell function affect major tissues and organs. In the United States, the maximum daily calcium intake judged likely to pose no adverse health effects—Tolerable Upper Intake Level (UL)—is set at 2,500 mg per day for all ages beyond one year of age. There are insufficient data to determine a UL for calcium for infants less than one year of age.

**Summary.** Changes in dietary calcium requirements throughout the lifespan reflect concurrent alterations in growth rate, intestinal absorption efficiency, and reproductive and estrogen status. Because calcium plays vital roles in critical cell responses, plasma calcium levels are strictly homeostatically controlled at the expense of skeletal integrity, if necessary. Homeostatic control of circulating calcium involves PTH, vitamin D, and calcitonin.

Appropriate lifestyle choices (for example, physical activity) and adequate calcium nutrition promote optimal bone-mass accretion during growth and young adulthood, possibly resulting in reduced current and future fracture risk. Dairy products and dietary supplements provide similarly adequate amounts of calcium to the body. Grains, fruits, and vegetables contain smaller amounts of calcium, and calcium absorption from foods high in oxalic acid or phytic acid is limited. Calcium-enriched products such as bread and fruit juice are becoming increasingly important sources of dietary calcium.

#### CALIFORNIA. See United States.

**CALORIC INTAKE.** The calorie is a unit of heat energy required to raise the temperature of 1 gram (1 milliliter) of water 1°C from 14.5° to 15.5°C. The calorie is a very small unit; and although it is used colloquially, the energy measured is 1,000 gram calories or kilocalories (kcal). Another unit of energy is the joule: 1 kcal = 4.184 kJ. Calories are used as a unit to measure the energy in food as well as the energy produced, stored, and utilized by living organisms.

#### Calories in Food

Foods are comprised of carbohydrates, fats, proteins, vitamins, minerals, and water. The energy-yielding nutrients

**TABLE 1**

<b>Caloric content of common foods</b>			
<b>Food</b>	<b>Serving size</b>	<b>Weight (grams)</b>	<b>Calories</b>
Beer	12 fl. oz.	356	146
Cheddar cheese	1 oz.	28	114
Margarine	1 Tbsp.	14	50
Apple	2 <sup>3</sup> / <sub>4</sub> in. diameter	138	80
White bread	1 slice	25	65
Doughnut, cake plain	3 <sup>1</sup> / <sub>4</sub> in. diameter	50	210
Rice, white	1 cup cooked	205	264
Beef patty	3 in. X <sup>5</sup> / <sub>8</sub> in., 21 percent fat	85	236
Chicken breast, fried	1 piece batter dipped	140	364
Broccoli	1 cup cooked	180	50
Corn	On cob, 5 in. long	77	83

are carbohydrates, fats, and proteins. When foods are oxidized or burned, they yield approximately 4.0 calories/gram for proteins and carbohydrates and 9.0 calories/gram for fats. Most foods contain mixtures of the three macronutrients but are classified by the predominant nutrient. For example, protein-riched foods such as beef also contain fat. Table 1 presents a sample of ten common foods, their weights, serving sizes, and calories. Daily caloric consumption is assessed in a number of ways: 24-hour dietary recalls, food intake diaries, weighing food before it is eaten, and using food labels on packaged foods.

In the early to mid-1990s, world food supply estimates of available calories per person per day ranged from 2,099 kcal in sub-Saharan African countries to 3,600 kcal in North America with averages of 2,573 kcal for developing countries and 3,356 kcal for industrialized countries. The percentages of calories are estimated to be 70.4 and 52.3 from carbohydrate, 19.6 and 35.4 from fat, and 10.0 and 12.3 from protein for developing and industrialized countries, respectively.

The energy requirements for humans are established by national and international organizations (for example, World Health Organization). The Recommended Dietary Allowances (RDAs), or more recently, the Dietary Reference Intakes (DRIs) are shown in Table 2. These caloric recommendations are based on the average needs for an individual based on age and sex with additional allowances for pregnancy and lactation. Restricted intakes lead to growth faltering in weight and height; and conversely, a surfeit of calories leads to excess energy stores and obesity. For example, a short and thin, preadolescent child with a slow rate of growth along the fifth percentile requires about 17 percent less dietary energy than a child following the average growth trajectory at the fiftieth percentile.

### Energy Expenditure

Caloric needs are based on energetic demands related to body size and activity. Overall caloric demands per kilo-

gram of body weight are extremely high from conception through infancy, and decrease thereafter. Total Daily Energy Expenditure (TDEE) is a combination of the Basal Metabolic Rate (BMR) sometimes called the Resting Metabolic Rate (RMR) and Physical Activity Level (PAL). The BMR is the minimum energy expenditure for maintenance of respiration, circulation, body temperature, and other vegetative functions. It is based on body size, growth, reproduction, diurnal hormonal variation, other physiological conditions, and thermoregulation related to environmental temperature. The BMR accounts for approximately two-thirds of the TDEE. In addition, about 10 percent of energy intake is expended in dietary thermogenesis or the energy costs of processing food.

Metabolic rate can be obtained by direct calorimetry that measures the total quantity of heat liberated from the body in a specially constructed chamber. With direct calorimetry, a young male with an average American diet generates 4.82 calories for every liter of oxygen consumed. Because direct measurements involve expensive equipment in a laboratory setting, most of the calculations for caloric needs are done with indirect calorimetry. Indirect calorimetry uses the differences in the concentrations of inhaled and exhaled oxygen to estimate energy use. The law of conservation of energy states that there must be a balance between all forms of energy expended or absorbed.

Reference equations are used most frequently to estimate energy needs and expenditures. Sets of reference

**TABLE 2**

<b>Recommended dietary allowances for energy</b>	
<b>Age (year)</b>	<b>Energy (kcal)</b>
<b>Infants</b>	
0.0–0.5	650
0.5–1.6	850
<b>Children</b>	
1–3	1,300
4–6	1,800
7–10	2,000
<b>Males</b>	
11–14	2,500
15–18	3,000
19–24	2,900
25–50	2,900
51+	2,300
<b>Females</b>	
11–14	2,200
15–18	2,200
19–24	2,200
25–50	2,200
51+	1,900
Pregnant	+300
<b>Lactating</b>	
1st 6 mo.	+500
2nd 6 mo.	+500

equations for BMR and standard energy expenditures for activities or PAL are routinely used in assessing an individual's TDEE. For adults, PAL ranges from 1.4 to 2.10 for light to very heavy work. For example, daily energy expenditure for a 120-pound (54.4-kg) woman who has a sedentary office job would be approximately:

$$\text{BMR} = 14.7(54.4) + 496 = 1,296 \text{ kcal}$$

$$\text{TDEE} = \text{PAL} \times \text{BMR} = 1.56 \times 1,296 = 2,022 \text{ kcal.}$$

Body weight is a key variable in energy expenditure. Walking at 3.5 miles/hour expends 0.035 kcal/min which would be 3.9, 5.2, and 7.0 kcal/min for individuals weighing 110, 150, and 200 pounds, respectively.

Individual differences in metabolic mechanisms are not well understood. Remarkably, for most adults, the sensitivity of the energy balance system for change is less than one percent per year. The "average" American adult male contains 140,000 kilocalories of energy in body fat, 24,000 kilocalories in protein, and only about 800 kilocalories in carbohydrate. Consequently, an individual consuming 2,000 kilocalories per day of which 40 percent is carbohydrate will ingest an amount of carbohydrate comparable to body stores, protein intake will average only about one percent, and fat intake will be considerably less than one percent of total body stores.

### Weight Control and Energy Balance

Caloric intake and expenditure are factors in the growing worldwide epidemic of obesity. It is estimated that in the United States, 35 percent of adults eighteen years of age and older are overweight or obese based on weight for height standards. The rising prevalence of obesity is due to an increase in intake of calorically dense foods and a decrease of energy expenditure with modernization, including increases in transportation, decreases in subsistence activities, increases in thermally regulated environments, and decreases in energy demands due to chronic illness. Weight reduction hinges on reducing caloric intake while maintaining micronutrient balance and fiber and water intake. Traditionally, recommended diets were labeled by their caloric content, such as the "1,200 calorie diet." Some diets have focused on the reduction of fat because each gram of fat is twice as calorically dense as a gram of carbohydrate or protein. Interventions also emphasize increased voluntary energy expenditure through daily routines such as walking or formal exercise programs. Pharmacological interventions directly influence energy balance by increasing BMR, decreasing absorption of fat calories, or decreasing transit time through the gut, and indirectly by altering hunger and satiety.

Low-energy intake compromises growth in vital tissues, lowers basal metabolic rate, and reduces work capacity relative to individuals with sufficient energy intake. People develop behavioral strategies to reduce muscular activity to conserve energy. For undernourished populations, interventions target increasing caloric intakes and reducing macro- and micronutrient deficiencies.

Finally, energy in kilocalories or joules has been used for measuring the flow of energy through ecological systems. Energy flow analyses measure time and task allocations in various subsistence activities as well as the biological characteristics of human and nonhuman populations in an ecosystem.

**CALORIE.** The calorie is a unit for measuring heat energy, and it is usually used as the unit for food energy and of energy expenditure. Media and lay attention to food, exercise, and health, as well as the greater prevalence of obesity during the past few decades, has resulted in a cultural preoccupation with caloric intake and expenditure in industrialized nations. Heat is that which produces a change in temperature. Heat was formerly regarded as a substance called "caloric," but it came to be viewed as the random motion of molecules.

The calorie has traditionally been defined as the amount of heat required to raise the temperature of 1 gram of water by 1.8°F (1.0°C), usually defined as from 58.1°F to 59.9°F (14.5°C to 15.5°C), under normal atmospheric conditions. Because electrical measurements can be standardized more accurately than heat measurements, a calorie is officially defined as equivalent to 4.186 joule. A joule is defined, in "force × distance" units, as 1 Newton meter, which is equal to (1 kg m/s<sup>2</sup>) × (1m) or 1 kg m<sup>2</sup>/s<sup>2</sup>. Energy values are expressed as joules when

the *Système International d'Unités*, which is recommended for all scientific purposes, is required.

Food energy values and energy expenditures are commonly expressed as the number of kilocalories (kcal). One kcal is equal to 1000 calories or 4.186 kJ or 0.004186 MJ. Although the terms "calorie" and "large calorie" have frequently been used in place of kilocalorie in the nutrition literature and for food labeling purposes, these alternative terms are confusing, and their use is discouraged.

### Measurement of Energy Values of Foods

The energy in foods is present as chemical energy; it can be measured by the heat evolved when the food is oxidized or combusted. Although energy transformations normally involve friction and heat conduction, which cause the changes of one form of energy to another to be incomplete, various forms of energy normally can be converted completely to heat. The caloric value of a food may be determined by burning weighed samples of the food in an oxygen atmosphere in an apparatus called a calorimeter, which is designed to allow measurement of the heat released by combustion of the fuel or food. The total amount of heat produced or consumed when a chemical system changes from an initial state to a final state is independent of the way this change is brought about (the law of Hess or the law of constant heat sums). Thus the complete oxidation of a compound, such as glucose, to  $\text{CO}_2$  and  $\text{H}_2\text{O}$  produces the same amount of heat whether the process is carried out in a calorimeter or by metabolism within the body.

Heats of combustion are not accurate reflections of the amount of energy available to the body, however, because the body does not completely absorb and metabolize ingested nutrients. The energy lost in the excreta (feces and urine) must be subtracted from the total energy value of the food to obtain the amount of energy available to the body from consumption of the food. The caloric values of foods reported in food composition tables are "physiological fuel values," also referred to as "available energy" or "metabolizable energy" values. They are not total energy values.

### Physiological Fuel Values of Foods

The physiological fuel value of a food or a food component may be determined by measuring the heat of combustion of the food in a calorimeter and then multiplying the heat of combustion by correction factors for incomplete digestion and incomplete oxidation of the food in the body. In about 1900, Wilbur Olin Atwater and his associates at the Connecticut (Storrs) Agriculture Experiment Station used this approach to determine the physiological fuel values of a number of food components (i.e., the protein, fat, and carbohydrate isolated from various foods). They determined factors appropriate for individual foods or groups of foods, and they proposed the general physiological fuel equivalents of 4.0, 8.9, and 4.0 kcal per gram of dietary protein, fat, and carbohydrate res-

pectively for application to the mixed American diet. These factors are commonly rounded to 4, 9, and 4 kcal per gram (17, 36, and 17 kJ per gram) respectively for protein, fat, and carbohydrate. The conversion factors determined by Atwater and his associates remain in use in the twenty-first century, and energy values of foods are calculated using these factors. The energy values (physiological fuel values) reported in food composition tables are commonly estimated by determination of the proximate composition of each food (i.e., the water, protein, fat, carbohydrate, and ash contents) followed by multiplication of the amount of each energy-yielding component by the appropriate conversion factor.

**CANADA.** Canada is a vast country touched by three oceans, and it holds within its boundaries prairies, hills, mountains, semidesert and desert country, rocky thin-soiled lands, a multitude of lakes, enormous forests, and Arctic tundra. While the terrain varies greatly, there is a commonality across Canada, and that is the severity of winter. Few European immigrants in Canada's early history were prepared for the cold, and from the beginning, Canadians struggled with the elements for their survival. This was a defining factor in the development of Canadian cuisine. But it is the people of Canada who, more than the land and weather, created Canada's cookery. From the First Nations people to the waves of immigrants from every country in the world, Canada's cuisine became distinctly regional.

Diversity has been a characteristic of Canadian cuisine from the beginning of settlement. In the seventeenth century, the first Europeans in Canada encountered a highly varied population of Native Peoples, for example, hunters and gatherers including the Inuit in the Arctic; agricultural people in parts of southern Quebec and Ontario; buffalo hunters on the plains; and fishermen on the West Coast among the nearly sedentary Pacific North Coastal people.

By the end of the eighteenth century, the dominant groups in Canada were British (particularly English and Scots), French, and American Loyalists. The cuisine that

developed during the nineteenth and first half of the twentieth century reflected these influences. There were strong overtones of French cookery in Quebec, British influences in English-speaking Canada, and a strong import of culinary culture from the United States. While there were many ethnic groups in Canada by the end of World War II, British-American cookery dominated Canadian cookery. A partial exception to this generalization was the Chinese influence. Peasants from southern China immigrated to “Golden Mountain” (Canada or, more specifically, British Columbia) beginning in the 1850s. Many were employed in construction and the building of the railroad. As with other cultural groups, they were discriminated against, but they introduced Canadians to Chinese cuisine by opening Chinese restaurants in nearly every village and city across Canada.

In spite of the cultural dominance of English-speaking Canadians, other ethnic immigrant groups often settled in regional pockets where they maintained their language and their culinary traditions. Coming from

different regions in their home countries, they melded traditions together. For example, in the Ukraine, women made *pysanky* (eggs decorated with ritualistic symbols) according to their local traditions, but in Canada, they drew designs from many regions of Ukraine. Northern and Southern Italian foods such as pasta and polenta, likewise, were simply “Italian” in Canada.

Until after World War II, ethnic foods were rarely written about in Canadian food magazines or cookbooks, and ethnic recipes were highly modified. In a 1920s community cookbook, for example, a chop suey recipe was a mixture of fried hamburger, rice, tomatoes, and onions, baked for an hour; and spaghetti was cooked meat, spaghetti, onion, butter, green pepper, and canned tomato soup, baked with buttered bread crumbs; both were seasoned only with salt and pepper. In the 1970s the milieu changed when, under the leadership of Pierre Trudeau, Canada adopted a policy of multiculturalism. It then became the fashion to share ethnicity, and the easiest way was through cookery. The foods that ethnic

Like the United States, Canada is home to many ethnic communities. These Greek Canadians are preparing traditional Easter pastries in Vancouver, British Columbia. © ANNIE GRIFFITHS BELT/CORBIS.

groups had eaten in the privacy of their homes became *de rigueur*.

After World War II, fast-food eateries and chain restaurants serving inexpensive, mass-produced foods swept across North America. Franchises on the U.S. model were adopted and Canadians quickly developed their own fast food restaurants for hamburgers, fried chicken, and pizza. A favorite fast-food chain is Tim Horton Donuts, a coffee and donut shop. Popular Canadian restaurant chains that developed were “road houses” serving grilled foods and pasta. The Americanization of Canadian foods and foodways was influenced also by food articles in American magazines and by television food shows.

Canadian cuisine is strongly regional in character with American influences. The eating pattern of three meals a day, the popularity of many foods, the importation of fresh produce and manufactured foods, and the eating of particular foods at the feasts of Thanksgiving, Christmas, and Easter are common denominators of the cuisine of both the United States and Canada. The real difference is the highly visible regional cuisines of Canada, based on the available ingredients and the ethnic groups who settled in these regions. Canadian cuisine cannot be understood without examining these regional traditions.

### **Newfoundland: A Survival Cuisine**

From the early sixteenth century, the huge and lucrative cod fisheries on the coasts surrounding this island province and the Grand Banks offshore attracted fishing vessels manned by Basque, Portuguese, French, and British sailors. Before settlement, these groups salted cod in summer fish-drying camps, and then dried it on “flakes.” A product that could keep indefinitely, salt cod was eaten in Europe for centuries. Eventually the Eng-

lish settled in the north and west, followed by the Irish, in St. John’s and the east coast, and French along the south shore. Newfoundland’s environment is harsh and demanding with deceptively warm but short summers. The cuisine that developed was simple and entrenched.

Only a few ingredients are needed to make rib-sticking, hearty, and soul-satisfying meals. Fish (cod) and root vegetables form the basis of the Newfoundlanders’ diet. There is little agriculture on the island, but root vegetables can be grown there, and tiny vegetable garden plots are often found along the roadside on the western coast. Potatoes, carrots, onions, turnips, parsnips, and cabbage are mainstays.

In 1992 the cod stocks crashed on the Grand Banks, and a moratorium was placed on commercial fishing in Canadian waters on the Banks. Although a way of life for Newfoundlanders seemed to have been lost, cod remains their favorite food. While the major cod fisheries are still closed, some fish is available on the southern coast, and local inhabitants are allowed to “jig” for cod two weeks a year. When a Newfoundlander says the word “fish,” he or she means “cod,” which, over the centuries, has been the preferred dish. A fresh cod dinner is Newfoundland comfort food. A thick piece of cod, usually grilled or poached, is served with mashed potatoes, mixed peas and carrots, coleslaw and fluffy white rolls. Delicacies are cod tongues and cheeks, either sautéed or deep-fried. Salt cod is prepared most commonly as fish ’n’ brewis (also called “fisherman’s brewis”). The salted fish is soaked, shredded, and cooked with dried bread chunks (hardtack) until thick, and *schruncheons* (fried diced salt pork) with its fat is poured over the mixture.

Pea soup (a thick potage of yellow split peas with diced turnips, carrots, and potatoes) can be traced back to the daily fare of sixteenth-century fishermen—with salt beef added on Sundays. Split peas are also used to make *pease pudding* by dropping a pudding bag of peas into Jigg’s dinner, a boiled dinner of salt beef, onions, potatoes, carrots, and turnips.

To supplement and vary the fish and salt-beef diet, many men hunt partridge, ptarmigan, rabbits, turr (a seabird), moose, caribou, and deer. Moose is preferred only because it will fill the hunter’s freezer—and his neighbors’—and last through the winter. A traditional wild-game dish is *flipper pie* made from seal flippers, carefully prepared and cooked in a pastry. The wilds also provide berries in abundance, eaten fresh and preserved for the long winter, either frozen for pies and other desserts or made into jams. Favorites are blueberries, strawberries, blackberries, raspberries, partridgeberries (*lignonberries*), and yellow baking apples (*cloud berries*).

More than anything else, Newfoundlanders are known for fun: parties, Newfoundland fiddling, and rum. *Screech*, a dark rum, was named because American servicemen during World War II found it made them “screech.” Those “from away” may undergo a New-

foundland initiation by tossing back Screech and reciting an intonation, always with good humor, and sometimes accompanied by kissing a cod.

### The Maritime Provinces: An Entrenched Cuisine

The cuisine of the Maritime provinces of Nova Scotia, New Brunswick, and Prince Edward Island (P.E.I.) is a bittersweet one—bitter because so many people were dislocated, either within the Maritimes or because they had to leave their homelands, sweet because the Maritime cuisine was a result. Early migration into the Atlantic provinces generally took place of necessity. Power struggles between France and England led to the forced displacement of the French Acadians in 1755, and American planters took over their rich farmlands. Scattered to many countries, some Acadians returned after 1763, not to their rich farmlands but to less desirable land, or they turned to fishing. Settling in parts of New Brunswick, Nova Scotia, and Quebec, they developed a distinct cuisine in each area: buckwheat pancakes, *poutine râpée* (dumpling stuffed with salt pork), *râpure* (grated potato and chicken or seafood pie), *fricots* (stews), rabbit pies, and many other traditional dishes.

Later in the century, in 1783, United Empire Loyalists, scorned in the United States, made their way into the Maritimes. These American Loyalists brought New England food traditions, popularizing corn in many forms (corn-on-the-cob, johnnycakes, corn puddings, and Anadama or Yankee bread), and the Saturday night custom of baked beans and brown bread. Freed African loyalists and others of African descent also came north. Blacks settling in the Shelburne area brought Southern American cooking: deep-fat frying, barbecued meat, the use of corn meal and hominy, pork, rice, and fish. Germans left for Lunenburg, Nova Scotia, in 1753 and contributed Solomon Gundy (pickled herring), soused eels, and sauerkraut. Scots in Cape Breton brought oat cakes and porridge bread. These early settlers created distinct regional cuisines. But the one traditional meal common to the Maritimes is Dutch mess, also called hugger-in-buff, fish and schrunchions, or house bankin, depending upon where one lives. Salt cod is soaked, then cooked; potatoes are boiled in the fish broth; salt pork and onions are fried, vinegar and cream added and poured over the cod and potatoes. The next day, leftovers are mashed and made into fish cakes.

The abundant fish and shellfish were the key ingredients defining early Maritime cuisine, and they continue to do so today. These seafoods, along with root vegetables, dried peas, cabbage, and trade goods from Britain formed the basic components used in early eastern Canadian cookery. Early English colonists were dependent upon Great Britain for food, and these supplies grew into a thriving trade of tea, sugar, spices (ginger was a favorite), and dried fruits. The triangular trade between England, New England, and the Caribbean brought molasses, rum, and ginger from the Caribbean. Halifax, the

### THE ORDER OF GOOD CHEER

The small band of French explorers at Port Royal, Nova Scotia, anticipated the winter of 1606 with dread. The previous winter many of their men had died from a mysterious “land-sickness.” The illness was thought to be caused by ill-temper, idleness, and discontent. Samuel de Champlain, a member of the band, founded *L'ordre de bon temps* (the Order of Good Cheer) to prevent the illness. The object of the society was to go hunting and fishing for wild game and seafood that could be served up in a series of feasts held throughout the winter.

The feasting was met with great enthusiasm by Chief Henri Membertou and his Mi'kmaq followers, who joined the hunting forays and were invited to the grand dinners. It was the custom of the Mi'kmaq to share their food with whoever was in the vicinity, and the French reciprocated this generosity. The variety of raw ingredients for their meals was extensive—venison, moose, beaver, ducks and geese, salmon and trout caught through the ice, scallops, cockles, sea urchin, crabs, and lobster. In addition to these foods, there was plenty of wine and provisions from France.

Although we do not know the dishes prepared for the feasts, the gentlemen in the group were accustomed to sophisticated food. Champlain had been a visitor to the court of Henry IV; one of the men wrote in his diary that their food was as good as roastmeats from the cook shops of Paris. As well, Champlain kept stocked fish ponds near the Habitation.

The Order did help to fend off the illness (scurvy) during the winter. More than anything else, however, the lasting benefit of the dinners was an enduring friendship between the Mi'kmaq and the French. As others have found, the dining table is much better than a negotiating table for mediating conflicts between cultures. The spirit of the Order of Good Cheer is a culinary legacy to Canadians.

early center of British social life, retains a distinct English character. Gaily signed pubs serve meat pies and fish and chips. British dishes linger—roast beef with Yorkshire pudding, trifle, and gingerbread.

Each Maritime province has vast coastal areas, and cod is common to all. Products of the sea vary somewhat in each province. Prince Edward Island is associated with lobster fisheries, aqua-cultured blue mussels, Malpeque oysters, and Irish moss. Nova Scotia is known for Digby scallops and dulce (a reddish seaweed). New Brunswick

## POOR MAN'S FARE

*Pâté à la râpure* (or rappie pie, the English name) is a traditional Acadian dish with its roots in the frugality of French women. After the British victory in Nova Scotia in the late eighteenth century, some families who had been expelled from the fertile Annapolis Valley returned, but to fishing or to farming marginal land. Times were extremely hard, but they were able to cultivate potatoes—and the men liked their white shirts starched. The women made starch by grating potatoes, squeezing out the starch, and boiling the white shirts in the extract. Since they couldn't waste the potato gratings, they put them into a pan with lobster or fish and baked this mixture. The result, distinctly different from sliced and baked potatoes, was a gelatinous, translucent mixture flavored with seafood, called *râpure*. Today the tradition continues and, although they still squeeze out the starch to give *râpure* its distinct character, the starch is seldom used for stiffening white shirts.

fishes for Fundy salmon, smelt, trout, and shad. Samphire greens (eaten locally) are harvested from the shores of each of these provinces. In countryside Nova Scotia, roadside “canteens,” one-room buildings, sell some of the region's best seafood: lobster or clam rolls, fried scallops, or fried fish—all seafoods cooked fresh from the sea.

The harvest from the land is also regional. Nova Scotia is known for its Annapolis Valley apple orchards, New Brunswick for its maple syrup and wild chanterelles, and P.E.I. for its potatoes. New Brunswick fiddleheads from the Ostrich fern are a gourmet delicacy picked in early spring before the fronds open, and are cooked as a vegetable.

By the early 1800s, established food traditions had become associated with a way of life, and to a great extent, have remained impervious to change. Even the large migrations of ethnic groups after World War II were insufficient to displace these three-hundred-year-old culinary traditions.

### Quebec: A Distinct Cuisine

Quebecois consider themselves a distinct society, and this is reflected in their cuisine. Restaurant menus are written in French, and the cuisine is distinctly French, but with a difference: most of all, the love of—even obsession with—good food and its celebration, the use of flavorful sauces, the elaboration of courses, the use of fresh ingredients, and the respect for their chefs. The first Eu-

ropean settlers in Canada in the early seventeenth century were French. They maintained close ties with their mother country until after the English conquest in the mid-eighteenth century. At that time, communication with France was cut off.

Thus, many traditional Quebec dishes resemble those prepared in medieval and early Renaissance France. Well-known favorites across Quebec are *cretons* (a rich pork pâté), *tourtière* (meat pie), *ragoût de pattes et de boulettes* (pigs' feet and meatball stew), *les cipaille* or *cipâte* (baked casserole made by layering pastry with meat, poultry, and/or seafood), and *galettes de sarrasin* (buckwheat pancakes). A hearty fare, originally cooked for fishermen, farmers, and loggers, they are today reserved for family gatherings and holidays.

The abundance of wild game and the land available to provide forage for it probably influenced Quebec's cuisine more than any other factor. This provided ordinary settlers with meat and gave them an equality with royalty unknown to the seventeenth-century French peasant. Indeed, in France at that time, food was frequently scarce. It is not surprising that the Quebecois' diet was rich in meat, poultry, and fish and that regional dishes were made with these ingredients.

Although maintaining their French heritage, the Quebecois incorporated ingredients and dishes from other cultures. From the beginning, the French had close ties with aboriginal peoples whose culture dictated that they share game and fish with their friends. The Native Peoples showed them the edible wild flora and fauna, and the French were quick to incorporate wild game, berries, and maple sugar into their diet. It should be noted that corn, beans, and squash had already been introduced into France before Quebec was colonized, and potatoes are thought to have been introduced by the British. American Loyalists and British immigrants after 1755 also influenced Quebec cookery; the French especially liked sweet British desserts, many of them made with molasses. Cultural influences continue today as with the Middle Eastern innovation *mechoui*, a popular party at which a whole animal is barbecued, usually wild game like buffalo or wild boar. Quebec cities, like other Canadian centers, have a multicultural character. This is especially true of Montreal, where there are more French-speaking immigrants than in other major Canadian cities: Haitians, Lebanese, and Vietnamese have all influenced Quebec's cookery, particularly in their family-owned restaurants and their ingredients in small grocery stores. Moreover, Montreal's population contains a mix of people speaking a multitude of languages who have contributed their foodways to the cultural mix of this city.

Quebec's cuisine is a highly regional one. The Institut de Tourisme et d'Hôtellerie du Québec has identified at least seventeen gastronomical regions within the province and has searched out more than 30,000 regional recipes. In the Gaspé, for instance, salt is used liberally

and salmon layered with pastry is their version of *cipâte*. People from the Lac Saint-Jean area are called “*les Bluets*” (blueberries), and these berries are made into *grandpères* (dumplings cooked in blueberry sauce) or a blueberry *cipaille*. Gourgane beans brought from Europe are unique to this area and are often made into *soupe aux gourganes*, a filling bean, barley, and vegetable potage.

Today, young Quebec-trained chefs search out local ingredients, experiment with them, and to some extent are turning to France for inspiration. Artisanal breads, soft cheeses, goat cheeses, Normandy-style apple cider, local wines, organically grown vegetables, white asparagus, fresh herbs (especially summer savory), wild mushrooms, rabbits, caribou, and wild game birds are some of the ingredients finding their way onto the Quebec table. The Quebec diet is changing but the accent remains distinctly French Quebec.

### Ontario: A Dynamic Cuisine

The French and then the British and, shortly thereafter, American Loyalist immigrants had close contact with members of the Iroquoian tribes. From these original farming inhabitants, the immigrants learned how to plant corn, beans, squash, Jerusalem artichokes, and sunflowers, and to tap the maple trees for their sweet sugar. In the early days of settlement, wild game and fresh fish from the streams and the many lakes in Ontario were plentiful. The French left little impact upon Ontario's cuisine, but the English foodways became dominant: their style of eating and especially their love of sweets, roasted beef and pork, cooked root vegetables, white bread, and tea. One of the first tasks the settlers had was to build grist mills to grind wheat for their cakes and breads. They found the farmland in southern Ontario to be fertile, and most of the crops from their homelands flourished. Dairy herds were established, which led in the nineteenth century to a significant trade in cheddar cheese with England and the popularity of this cheese in Ontario.

There were two influential groups who came north with the Loyalists at the end of the eighteenth century. The Iroquois under the leadership of Joseph Brant settled near Brantford to form the Six Nations. An agricultural people, they grew the “Three Sisters”—corn, beans, and squash—and reinforced the growth and use of these crops in Ontario. The other group was the Pennsylvania German Mennonites who took up farming in the Waterloo area. When the Ontario Mennonites chose their food preparations from the Pennsylvania German recipe repertoire, a difference appeared. While the recipes they loved best were still distinctly Mennonite, the choices of foods changed. In Ontario, they are known for summer sausages, *Nusschinken* (cool-smoked ham), smoked pork chops, *Koch Käse* (a runny cooked whey cheese flavored with caraway seed, smeared on bread with apple butter), shoofly pie made with maple syrup, Dutch apple pie, doughnuts, and mint tea.

### CABIN AU SUCRE

Where the sugar maples grow in Quebec, there will be “sugar shacks.” From the beginning of settlement, colonists tapped the clear maple sap to produce sugar for the year's use as a sweetener. “Spiles,” originally wooden tubes with sharpened ends and now metal tubes with hooks for buckets or tubing, were placed in holes drilled into the sugar maple trees. When the nights were cold and days warm, the sap flowed. In the old days, horses hauled tubs of the clear liquid to a covered shed where the sap was boiled down day and night. It took thirty to forty buckets of sap to produce one bucket of golden maple syrup. Men and boys stayed for weeks in the bush tending the fires and watching the syrup so that it would not burn. Today, when one drives through Quebec in the early spring before the snow melts, buckets adorning maple trees and smoke billowing from the bush are a common sight. From this, today's *cabin au sucre*, or sugar shack, has become a Quebec feature that anyone can enjoy. City folk today flock to the *cabins au sucre* to feast on maple-drenched dishes, to dance, and to drink. Outdoors, children are treated to *la tire*, syrup boiled down to a taffy and hardened on snow, and horses draw wagons of fun-seekers into the bush to view the miles of plastic tubing collecting the clear sap—Quebec “gold.”

In the nineteenth century, southern Ontario was the terminus of the “underground railroad,” offering shelter to American blacks escaping slavery. They brought Southern American cookery to Ontario. Irish, Scots, English, and other groups streamed into Ontario during this century, reinforcing British cuisine. Rutabagas (called turnips) were standard winter fare. Steamed carrot pudding became a Christmas tradition. China tea cups were given to brides, and the prescribed wedding cake was a dark fruit cake.

Some ethnic groups entering Ontario in the nineteenth and twentieth centuries formed communities around Ontario: the Poles in Wilno, the Portuguese in Strathroy, the Italians in Guelph, the Scots in the Renfrew valley near Ottawa, the Finns in Thunder Bay, and Ukrainians and Eastern Europeans in Hamilton. This is not to say that myriad cultural groups are not found in these areas; the point is that in these areas, the home cuisine and the language of these settlers was maintained.

Coming primarily from politically troubled parts of the world, approximately 175,000 immigrants annually

enter Canada. Of these, about half locate in Ontario, the majority moving into the Toronto area. Immediately after World War II came Italians, Eastern Europeans, British war brides, and many others. In the 1970s, after Canada's newly entrenched multicultural policy, immigrants streamed in from Hong Kong, Vietnam, Somalia, Ethiopia, Croatia, Serbia, India, Sri Lanka, the Middle East, and other countries. Ontario had long served up a meat, potato, and root vegetable table, but the influx of new people and their culinary traditions meant a developing and rapidly changing gastronomy in Ontario, led by Toronto.

Toronto, the most culturally diverse city in Canada, is a reflection of Canadian multiculturalism in the makeup of its population and in its cuisine. There are five Chinatowns in the Toronto area, most recently settled by affluent Chinese from Hong Kong, and Chinese restaurants represent every region in China. Upscale restaurants serve Italian, Portuguese, Greek, Indian, Lebanese, Caribbean, and American cuisine, but the neighborhood dining spots are the best places to find the comfort food of nearly every nation in the world and at a reasonable price.

As a result of this diversity, Ontario is somewhat fragmented in its cuisine, but people in Ontario pride themselves on a receptivity to the flavors of the world. Hoisin sauce, *garam masala*, *baba ghanoush*, phyllo pastry, flat breads, *tzatziki*, pierogies, rice and beans, Jamaican meat patties, and espresso are, if not daily fare, part of Ontario's food repertoire.

### The Prairies: Bread and Beef

Traveling west through the provinces of Manitoba, Saskatchewan, and Alberta, seemingly endless fields of wheat dominate the landscape. The wheat belt runs through all three prairie provinces, and wheat is an important economic export. Canadian cuisine has been affected by this bountiful crop since it was first planted on the Prairies in the last half of the nineteenth century. Canadians have a history of baking. In 1913 Five Roses Flour Company published a cookbook of recipes collected from women across Canada. By 1915 this book was found in 950,000 or nearly half of the homes in Canada. In addition to bread and pastry flours, durum wheat that is made into semolina flour for making pastas is grown here.

Prairie history, however, was not one of farming. Native Americans who dominated the plains lived primarily on buffalo, which they preserved by drying and mixing it with buffalo fat and berries, usually Saskatoon berries, and storing the mixture, known as pemmican, in containers made of buffalo skin. French and Scottish voyagers of the fur trade were provisioned with pemmican by Native People, and early settlers relied upon it. When overhunting led to the demise of the huge buffalo herds, beef took its place. A favored method of beef cookery is

grilling, and some cook it outdoors year round. For community barbecues, a hole is dug with a backhoe large enough for several cords of wood and an entire beef animal. After twelve hours of underground cooking, the beef is sliced and served with baked beans, fresh breads, salads, pickles and relishes, pies and cakes. Calgary, the home of the Canadian cowboy, glorifies the chuck wagon at "stampede," the annual rodeo. Chuck wagon races are an awaited event; the wagons dash pell-mell around a circle and at the finish line the cowboy "cook" must be the first to light the campfire. Chuck wagon expressions humorously included "baked wind pills" (baked beans), "CPR (Canadian Pacific Railroad) strawberries" (prunes), "dough-gods" (dumplings), "paperweights" (hot biscuits), and "yesterday, today and forever" (hash).

Until the 1950s, British settlers strongly influenced prairie cuisine. Stews, roast beef with Yorkshire pudding, and cakes named after British royalty (Prince of Wales, Prince Albert, King George and King Edward cakes) were popular. Today, Alberta is dotted with English tea houses, in as unlikely locations as a grain elevator.

While British cookery dominated the great wave of immigration (over a million) in the early part of the twentieth century, immigrant groups did not sacrifice their culinary traditions. Russian Mennonites settling in Manitoba, Icelandic immigrants in Grimli, Manitoba, Hutterites in Alberta, and the French who came early in settlement, particularly in Winnipeg, continued to cook their favorite recipes, as had their families before them.

Ukrainians, however, influenced prairie cookery. From the time they arrived at the end of the nineteenth century, they brought with them a tradition of wheat farming and cuisine. Mothers taught daughters the ancient art of making traditional breads and *pysanky*. They introduced *varenyky* or pierogies (flour-based rounds of dough stuffed with a unique Canadian potato and cheddar cheese mixture), stuffed cabbage rolls, *psyryzhky* (baked stuffed buns), and *paska* (Easter bread).

Newer immigration waves have made their mark on Prairie cuisine, particularly in the cities. In Winnipeg there is the largest Philippine population outside of that country. West Indian *roti* shops, Middle Eastern foods, and other ethnic foods add to the culinary flavors of Winnipeg, Edmonton, Saskatoon, and Calgary.

### British Columbia: Aboriginal, English, Chinese, and California Fusion

Because of settlement patterns in British Columbia, Canada's westernmost province, its cuisine is different from the rest of Canada. The aboriginal people included many bands of North Coastal and Interior Coastal Peoples living in small villages along the Pacific Ocean and in the interior mountainous areas. By the 1860s there was a genteel English colony on Vancouver Island enjoying garden parties and afternoon tea. Chinese laborers arrived in the last half of the nineteenth century, and in ad-

dition to opening restaurants, frequently became cooks in English homes. In the twentieth century, the Californian free-spirited cookery spread up the coast, espousing the use of fresh local ingredients and healthy cooking, including vegetarianism. Many other cultural groups added to this mix but the dominant cuisine is Aboriginal, English, Chinese, and Californian.

As the cuisine in British Columbia developed, locally grown or harvested ingredients from land and sea respectively were adopted by all groups and each modified them according to their backgrounds. The Pacific harvest focuses on salmon: coho, chinook, pink, chum, and red sockeye salmon. Halibut, black cod, lingcod, tuna, rockfish, and eulachon are also favored fish. Shellfish include crabs (especially Dungeness) oysters, scallops, shrimp, prawns, abalone, and many varieties of clams. Agricultural areas in the beginning were developed in the Fraser River delta, supplying produce for Victoria and Chinese vegetables for early Chinese immigrants. Further inland, microclimates characterize the agricultural areas of the Okanagan and Similkimen Valleys, the fruit-growing regions of British Columbia. This climate is ideal for viticulture, and some grapes left on the vine until January are made into Eiswein. Soapberries, thimbleberries, salmonberries, huckleberries, and many other berries are harvested from the wild, as are pine mushrooms growing in evergreen forests.

The first inhabitants who influenced British Columbian cookery were the North Coast Native Peoples. Salmon was and continues to be their primary foodstuff: it is baked, poached, barbecued, and smoked. Family smokehouses are common in the coastal villages. Women also preserve salmon by canning for times when it is not in season. Eulachon oil and herring eggs are prized foods. Eulachon, a small oily fish (also called “candle fish” because when dried it can be lighted), can be eaten fried or baked, but is prized more for its oil, used as a dip for foods and as a seasoning. Spruce boughs are placed in the ocean water and become a spawning site for herring. The branches are harvested with the eggs still clinging to them and are then dried. It is not uncommon to see these boughs drying on the sides of houses. Roots were gathered in the past but are not as commonly used today with the exception of roasted camas bulbs. Indian ice cream is made by whipping the indigenous soapberries into a froth. These local ingredients still dominate aboriginal cooking, particularly since food must be brought to many native villages by ferry. However, the overall cuisine of the Native Peoples has been affected by Canadian culinary culture and their daily menus are as likely to include pizza, burgers, donuts and coffee, stews, pies and cakes as that of any other Canadian. But they value their distinct culinary traditions.

Victoria on Vancouver Island, more than any other Canadian city, has a decidedly English character. Afternoon tea is still a tradition, and locally brewed ales can be found at English-style pubs. In the warm climate (by

French Canada is noted for its distinctive cookery, and the Old City of Quebec has capitalized on food tourism. Shown here is the Auberge du Tresor, a restaurant and hotel in the historic part of the city. © WOLFGANG KAEHLER/CORBIS.

Canadian standards), growers around Victoria are able to successfully harvest such fruits as kiwi and figs. Their small farms are often organic, and herbs are grown year-round.

Vancouver, the largest city in British Columbia, although multicultural, has a character all its own. Here there are English, Chinese, Pacific Coast Native, Italian, and Japanese, as well as Californian influences. The Chinese influence is strongest in Vancouver. The Chinese community demands fresh produce and fish—evident in Vancouver food stores. Chinese vegetables such as *gai lohn* have long been grown in the Fraser River delta. Live fish and shellfish from the Pacific are kept in tanks (goeduck clams, Dungeness crabs, and rockfish). Recent wealthy immigrants from Hong Kong created a demand for imported Chinese foods and medicines such as ginseng (grown commercially in British Columbia and Ontario), dried abalone, shark’s fin, and bird’s nest.

Young, well-trained chefs are combining this cooking in various adaptations, creating a fusion cuisine. These young people revere local ingredients, ethnic ideas and styles, organically grown foods, herbs, edible flowers, whole grains, and enjoy the good life.

### The North: Finding Food for Survival

Canada’s agricultural belt as well as its population is concentrated in approximately the lower one-third of its land mass. The “North” includes the territories of the Yukon, the Northwest Territories, and the newest territory, Nunavut. For purposes of describing the regional cuisines of Canada, the forest land south of the tundra and north of the agricultural belt are also included, as are parts of the Prairie provinces, Ontario, Quebec and Labrador.

Indigenous ingredients distinguish the cuisine of northern Canada from other regions. Because food supplies are difficult to transport, there is more of an emphasis upon local foods than in southern Canada.

Caribou, muskoxen, moose, deer, ptarmigan, and arctic char are hunted or fished. Today aboriginal people supply wild game to restaurants and the luxury market, particularly caribou, muskoxen, and arctic char. Migratory ducks and geese provide variety to the larder in the fall. Berries grow profusely—blueberries, partridge berries, cranberries, and black currants are made into pies, preserves, jellies, and sauces. These foods all have local habitats—not all are found in every part of Canada's north.

The aboriginal population comprises about two-thirds of the northern population. Before European settlement, the Inuit occupied the Arctic, that is, the tundra beyond the tree line that encompasses the northern third of Canada's land mass. The aboriginal tribes of the Mackenzie and Yukon River basins and the Northern Cree occupy the northern wooded areas. Before contact with Europeans, these Peoples of the First Nations were self-sufficient and lived seasonally, either following herds of caribou or moving from place to place where food could be found. Their diet was rich in protein, with plant materials making up an estimated five percent of their food. This diet was healthy and supplied all their nutritional needs. In the twentieth century, attempts to assimilate Native Peoples into white society changed the native culture dramatically. Many were moved to permanent settlements (especially the Inuit) and were no longer able to resume their migratory food patterns. They began to live on foods that could be transported into their villages, usually by plane. These foods were much different from their traditional diet. Carbohydrates were introduced, particularly white flour and refined sugar. Manufactured foods like potato chips and soft drinks became popular, especially because the traditional pattern was to eat when hungry rather than at set meal-times. Rich in fat and starch, these new foods were detrimental to the health of Native Peoples, leading to diabetes and other dietary diseases. While there is a trend among Native Peoples to return to their traditional diet, permanent settlements make this difficult.

The largest white settlements in the north are in the Yukon and Northwest Territories. Dawson and Whitehorse were settled during the gold rush, and Yellowknife was established as the capital of the Northwest Territories. The Yukon today has predominately British roots. The center of the gold rush beginning in 1897, Dawson drew miners, honky-tonk girls, and the Royal Canadian Mounted Police (RCMP). To prevent starvation, miners were required to pack in a year's supply of food before they were allowed into the territory. Provisions were basic and affected the cuisine of the territory: beans, flour, dried fruit, sugar, bacon, and tea were common items. Wild game supplemented their plain diets, but if they struck it rich they could buy luxury foods such as chocolate, champagne, and fresh eggs. Prospectors became known as "sour-doughs" because they craved white bread so much they baked it in their camps. Legend has it that

they kept the yeast starter alive by carrying it in their armpits when traveling in the bitter cold.

Today procurement of food for the north still requires a great deal of planning. Winter is unpredictable, and even where there are logging trails or water access to northern communities, food supplies are sometimes delayed. Nearly any food can be shipped in by air, but that option is expensive. With modern communications with the rest of the world, there is demand for many more food products, especially in increasingly popular luxury fly-in hunting and fishing lodges. Overall, diets in the North are simpler than elsewhere, but definitely Canadian in style.

From coast to coast, diverse regional cuisines dominate Canadian cooking. Canadians today value their ethnic origins highly and take pride in preserving their culture, particularly their cuisine. Overlying these regional cuisines is a dominant North American influence, which is not surprising since there was American immigration into Canada early in its history, the language is understood by most Canadians, and the cultural influence of the media has brought trends and new foods to Canada. Canadians also take advantage of fruits and vegetables grown south of the border that lend variety to winter meals. One cannot say that there is a national cuisine, as there is in Mexico, but one must experience and enjoy the diverse regional cuisines of Canada, which together create a diversity of foodways that reflect Canadian society.

## CANADA.

### NATIVE PEOPLES

There are over half a million Peoples of the First Nations scattered across Canada. Divided into more than 600 bands, nearly 60 percent live on reserves, the majority on the plains and the West Coast. Greatly differing in their background, culture, and traditional cuisine, the Peoples of the First Nations can be divided into cultural groupings, each with a distinct cuisine: the Woodland First Nations, the First Nations of Southeast Ontario, the Plains People, the Pacific Coastal Nations, the First Nations of the Plateau, and the First Nations of the Mackenzie and Yukon River basins. The Inuit, occupying one-third of the landmass in Canada, are another important aboriginal group with a different and distinct cuisine.

Inhabitants of Canada for thousands of years before European contact, the Native Peoples created markedly different cuisines from the raw ingredients available: local wildlife and indigenous plants. Although basic cooking methods varied from tribe to tribe, most peoples roasted food over hot coals and used the "stone-boiling" method of cookery. Food and water were placed in a wooden, bark, or skin container and hot rocks were dropped into the vessel to heat the water and cook the food. It was not surprising that iron kettles were highly prized when offered in trade by Europeans because they simplified this method of cookery. Salt was absent from their traditional food preparations as was frying food in fat. Both were introduced by Europeans along with new ingredients and preparations. Wheat flour was one of the first widely accepted foods and bannock became the traditional bread that spread to every tribe across Canada. New root vegetables such as carrots, onions, and turnips were readily added to their cooking pots for flavor and nourishment. It is thought that potatoes, brought to Eu-

### BANNOCK

Bannock is a bread universally loved and prepared in the homes of every aboriginal tribe in Canada. The Scottish fur traders are thought to have introduced this preparation. Folklore tells its probable origin. Scottish men, carrying a bag of flour in their canoe and not caring about amenities, made a well in the center of the flour, poured in water, and stirred it with their fingers to make a dough. Wrapped around a stick and roasted over the campfire, this bannock was shared with aboriginal guides.

Today bannock has many variations. Flour, a small amount of baking powder and salt, and sometimes a little fat, are placed in a large bowl and an indentation is made in the center. Buttermilk, milk, or water is poured in and the liquid is deftly and gently worked into the flour to form a soft dough. This is rolled out and cut into rounds and baked. The result is a tender, unleavened bread about two inches thick. It is also cooked in an ungreased skillet on top of the stove. When the bannock dough is fried in fat, it is called "fry bread" or "fried bread." In the out-of-doors, bannock is still baked over a campfire, either wrapped around a stick in the traditional manner or in a heavy iron skillet placed on hot coals. For variety, blueberries, saskatoon berries, or raisins are added to the dough before it is baked.

At powwows, bannock is a featured food. It is rolled into large rounds and deep-fried as a base for Indian tacos. This recipe first appeared on the powwow circuit between twenty and thirty years ago, and the fry bread base is topped with a seasoned bean or meat mixture, shredded cheese, chopped lettuce, and tomato. The fry bread can also be served hot with butter and honey.

rope from Peru by the Spaniards, were carried to Canada by Irish immigrants and these easy-to-grow tubers were quickly accepted in aboriginal communities. Refined, cheap sugar was a valued commodity and enjoyed in its many uses in sweet desserts and, later, in soft drinks. In the twentieth century, aboriginal people, like other North Americans, became enamored with manufactured foods including snack foods, rich in salt, fat, and sugar, and began to shop at their band or grocery stores for most of their food supplies. However, nutritional research has shown that their native diet was healthier than the new diet to which they were introduced. The incidence of diabetes and other dietary diseases is high among Native Peoples.

After initial contact, Europeans attempted to assimilate the Peoples of the First Nations into white culture, most recently by taking children from their families and placing them in residential boarding schools. Children were taught English and ate the white people's diet, but the Peoples of the First Nations remembered their past. There is a strong force within their communities to prepare traditional foods, and, at the same time, to improve their diet. Young aboriginal chefs are making their mark on Canadian cuisine. Specifically trained in courses on aboriginal cuisine and native culture, these young people are putting native cuisine on Canadian menus.

Although diverse in their foods and foodways, there is a commonality that crosses from Nation to Nation, and that is a deep spiritual relationship with the land and the life forms that inhabit it. The Peoples of the First Nations have a great respect for all living things and believe that human beings participate in a world of interrelated spiritual forms. Moreover, toward the end of the twentieth century, aboriginal peoples across Canada began a concerted effort to control their lands and resources.

### **The Woodland Peoples**

The Woodland Peoples include Mi'kmaq, Montagnais, Ojibway, Algonquin, Odawa, and Cree, the tribes who first met the French and formed alliances with them in the seventeenth century. Spread across the eastern provinces from Nova Scotia to Manitoba, they were hunting and gathering societies, migrating from place to place, following the seasonal movements of wild game animals. Moose, venison, beaver, rabbit, and caribou in the north were their quarry. Wild waterfowl and fish were also part of their diet, as well as berries that could be gathered. Wild game was prepared by the women, who either roasted the food or boiled it by dropping heated stones into water-filled bark containers.

Sharing food was part of their culture and many an early settler would not have survived had it not been for the native people who gave them part of the meat they hunted and taught them how to track game and use snowshoes. They introduced the French to maple sap, which they prized as a spring tonic and which could be boiled down to sugar. They showed them fiddleheads, the fronds of the ostrich fern, a gourmet delicacy in twentieth-century Canada. An important grain, part of the Ojibway diet, was wild rice, gathered in shallow bays by canoe. The Woodland Peoples no longer depend upon wild game, although hunting and trapping are still important.

The spiritual part of their culture remains integral to their life. For example, the Ojibway observe the seasons with festivals, beginning in the spring with the strawberry festival and the drinking of strawberry juice, giving thanks to their creator.

### **Peoples of Southeast Ontario**

At the time of contact, the aboriginal people who were farmers in Canada lived in Ontario (members of the Iro-

quoian tribes), and there were occasional farming settlements in Quebec. Fifteen varieties of corn, sixty of beans, and six of squash, including pumpkins, were grown. Jerusalem artichokes and sunflowers were also cultivated. Maples were tapped in the spring and the sap boiled down to sugar, used sparingly as a sweetener and sold to early settlers. The most important of their crops were corn, beans, and squash, the "Three Sisters," which together provided a complete diet. Food was cooked by the women in pottery containers, which they made. Fish and meat were added for flavoring but were a small part of their diet. Three festivals were held to honor corn: the corn planting, the green corn, and the harvest festivals.

The largest band in Canada is the Six Nations of the Grand River Iroquois in Ohsweken, Ontario, who came north with British Loyalists in the late eighteenth century. Their ceremonies are held in a modern building resembling a long house in style. For traditional ceremonies families bring food, fragrant sweet grass is burned, and the food is blessed. Corn soup is served at ceremonies and in homes. To make this special soup, women begin preparing it in late summer, first slowly drying white flint corn kernels in the oven and then storing them in containers. The soup is made by simmering the dried corn with fresh pork, kidney beans, and a little salt. Corn soup is also served at the "Snow Snake" in the winter, a contest in which the men throw a javelin-like spear down an icy groove (the spear may travel almost 3,300 ft., close to 1,100 yds.).

### **The Plains Peoples**

The Plains Peoples (Blackfoot, Blood, Peigan, Gros Ventre, Cree, Assiniboine, Sioux, and Sarcee [Tsuu T'ina]) followed buffalo migrations. Depending upon the tribe, after the slaughter the kidney, heart, or liver (all were considered sacred) was eaten first, raw. Animals were always slaughtered as needed, not for sport. Every bit of the buffalo was utilized for food, clothing, or shelter. The fresh meat was either roasted or cooked in a skin bag by the stone-boiling method. Jerky was prepared by sun-drying strips of meat, which were pounded almost into a powder and then mixed with buffalo fat and berries to make pemmican. Stored in a buffalo skin, it remained edible for years, and early European settlers and fur traders depended upon it. After the buffalo had all but disappeared, its meat was replaced by beef. Today, the Plains Peoples' favorite method of cooking beef is boiling it with potatoes, and the boiled meat is often served with pork cracklings. Tongue is a delicacy eaten during the Sun Dances. Kidneys, lightly grilled on the outside, are eaten by the Siksika of the Blackfoot. Intestines are stuffed with raisins, cooked, and eaten. Their tradition of not letting any part of the animal go to waste continues. Men of these tribes still consider themselves meat eaters and continue to hunt wild game for food and sport—deer, antelope, rabbits, and, near the Rockies, elk and mountain sheep, as well as other animals and birds.

## The Pacific Coast First Nations

The Pacific Coast First Nations (Haida, Tsimshian, Nootka, Coast Salish, Kwakiutl, and Bella Coola) live on the coast of British Columbia. By the time Columbus had reached the Americas, these people had developed an elaborate social structure. They lived in semipermanent communities in homes built with cedar boards, had extensive trade networks, and had sufficient leisure time for artisan carvers to develop.

A unique feature of these people was the potlatch, an elaborate feast publicly declaring and legitimizing a change in state—birth, marriage, death, or inheritance of rights. The chief who gave the potlatch provided enormous quantities of food, served in intricately carved containers, and invited guests from other tribes were expected to consume food until they could eat no more. During the feast the chief gave away his possessions, and the more generous he was, the more powerful he was thought to be. The potlatch was outlawed from 1884 until 1951, but was still held in secret. Potlatches today are held for the same reasons as in the past, and the potlatch ceremonies—singing, drumming, dancing, and speech-making—all reaffirm the community's cultural identity.

The planning for a potlatch may take several years. The community participates in preparing feast foods, which are a combination of their favorite traditional dishes and North American foods. Entire families attend the potlatch, including infants. Generally, two meals are served each day of the potlatch, a dinner and then a late supper break after midnight. Some of the traditional foods that are served include dried herring roe, grease from the eulachon (an anadromous marine food fish found along the north Pacific coast), seaweed soup with salmon eggs, and, always, salmon. These foods are accompanied by tossed salads, vegetables, pickles, bannock, and cakes. Speechmakers reiterate the "plentifulness of the food." Rituals are observed at the feast: elders and chiefs are served first, guests are considered rude if they refuse food during the meal, and all are invited to take food home. On the last night of the feast, boxes and boxes of goods are given to the guests. Today these gifts consist of a variety of goods such as mugs, glasses, housewares, T-shirts with the family crest, towels, and blankets. Valued foods such as dried herring eggs and eulachon grease are given to special guests, as are envelopes of money. The revitalized potlatch reinforces community cohesiveness and support for the leaders of the community.

## The First Nations of the Plateau

The First Nations of the Plateau (Interior Salish, Kootenay Tribe, Chilcotin, Tahltan, Tagish, and Carrier Sekani) occupy the great valley between the Rocky Mountains and the coastal ranges in British Columbia. These peoples, along with the coastal Nations, were the most numerous of any aboriginal group before European contact. Within these cultural groups, staple foods varied from northern to southern British Columbia. In the

central area, salmon, which spawned in the Fraser River, were the staple food, while in the north wild game, especially moose, deer, and caribou, was hunted. Researchers have identified more than 150 plants that were gathered and, in the southern area, supplied 50 percent of the calories consumed. Families or chiefs owned gathering areas and, although agriculture, *per se*, was not practiced, the grounds were tended and cared for so that plants would flourish and could be harvested annually. Roots were an important staple, especially Yellow Avalanche Lily, Spring Beauty tubers ("Indian Potato"), and bitterroot. Pit cooking was favored for cooking roots. A hole was dug, rocks added, a fire built to heat the rocks, and a protective layer of vegetable matter was placed over the coals. Foods were placed on top of this layer and carefully covered with more greenery and then with soil. Some water was added, and the whole cooked for hours. Wild berries, gathered by women, were eaten fresh or cooked and dried in wooden frames to make berry cakes, then stored for later use. These cakes were soaked and mixed with eulachon oil. The Interior Peoples had extensive trade with the Coastal Peoples and exchanged their roots, berries, and other goods for eulachon "grease," herring roe, and other goods. When potatoes, rice, flour, sugar, and other foods were introduced, they were readily accepted by the Interior Peoples. They still gather berries, root vegetables, and wild mushrooms. Their traditional foods are greatly valued even though many of their ancestral gathering grounds have been destroyed by cattle or development.

## The First Nations of the Mackenzie and Yukon River Basins

Small in numbers, the twelve tribes of the Mackenzie and Yukon River basins occupy one-fourth of Canada's landmass. They include the Chipewyan, Beaver, Slave, Yellowknife, Dogrib, and Hare tribes. Their traditional hunting lands, located just below the tundra, provided sparse vegetation for game animals, so family units had their own hunting grounds. Seminomadic, they followed migratory animals such as caribou. Where available, they hunted moose, mountain sheep, wood buffalo, and bear. Hunting was often a winter activity that required snowshoes, and snares were set to trap game. Fish were important, caught either through the ice in the winter or by canoe after the ice broke up in the spring. Game was boiled in birch bark containers using the stone-boiling method. All of the Yukon tribes held memorial feasts for their dead on the first anniversary of their death. Today, hunting is still an important part of their life and snowmobiles have allowed them to have a wider range in their winter hunting territory. However, permanent settlements and the decrease in caribou herds in some parts of their territory have diminished the emphasis on game as their major food supply.

In the twenty-first century, Native Peoples eat much like other North Americans. They buy their foods from

grocery or band stores, frequent fast-food restaurants and pizza parlors, get Chinese takeout, and drop into coffee and donut shops.

**CANCER.** See **Health and Disease.**

**CANDY AND CONFECTIONS.** Candy is a collective name for sugary treats such as fudge, taffy, bright colored gumdrops, and boiled sugar. Originally, "sugar candy" meant sugar concentrated to the point that it formed a hard crystalline mass on cooling. The term (derived ultimately from a Sanskrit root, through Arabic *sukkar quandi*) was first recorded in English in the late fourteenth century; the word "candy" used alone appeared in the eighteenth century. The equivalent word in British English is "sweets." "Confection" is a word with a wider meaning. Sugar-based candy represents one category of confections (and is the sense mostly discussed here). Chocolate is another category (though the fillings of bars may be candy). The idea of a confection extends to pastry, cookies, and cakes. The trade of the confectioner, who is skilled in making delicate sweet things, links these different areas of expertise together.

Five hundred years ago, "confection" meant a mixture made to enhance health. Confection originally had the sense of 'something put together', and confections in the fourteenth century were medicinal preparations made from combinations of various drugs. It was very quickly discovered that "a spoonful of sugar makes the medicine go down," and sweetening agents were added to the medicines. "Confection" was being used to mean 'a preparation of spices, sugar, fruits, etc.' by the middle of the

### CANDY CANES AND PULLED SUGAR

Striped candy canes, used for decorating the Christmas tree, are made by a technique known as pulling. For this, a concentrated hot sugar syrup is worked by stretching and folding, either by hand over an iron hook set in the wall or on a specially designed machine. After a short time, the sugar becomes opaque and white as pockets of air are folded into the mass and stretched. The basic lump of pulled sugar is made into a rough cylinder and decorated lengthwise with stripes and patterns made from colored boiled sugar (usually red). Then the mass is pulled out again (often by spinning on a machine) into long thin pieces. This process extends the sugar into thin ropes with decoration running through the whole length. Once the required diameter, usually about half an inch, is reached, the ropes are cut into shorter sticks. Candy canes are given an extra flourish by bending the top to give a shepherd's crook shape. Pulling is known in many other countries. In Britain it is used for "seaside rock," sold as a souvenir in seaside resorts. This is a sugar stick with letters or patterns running the length. In Sweden it makes the traditional mint-flavored *polkagrisar*.

Pulling is also used to make a more friable textured candy. The best-known example is probably Edinburgh rock, sold in the Scottish capital. For this, the sugar syrup is boiled to a lower temperature, and the sugar is allowed to grain after the candy is shaped. Similar confections include cinnamon-flavored *kaneel-brokken* (The Netherlands) and *peinir schekeri* (Turkey). Pulled sugar has an ancient and obscure origin. A description of the process is given in the *Kitab-al-Tabikh*, a collection of recipes written down in thirteenth-century Baghdad, but, as with other candy techniques, the skill was probably developed at a much earlier date somewhere farther east and transmitted westward with sugar cane and the knowledge of refining sugar itself.

fifteenth century. Confectioners preserved fruit, made sugarplums, marzipan, cordials, and light cakes. Sugar was important in these: it was expensive, exotic, sweet, and considered to be a spice with health-giving qualities. It was used to decorate other foods. In the English-speaking world, sugar became steadily cheaper through the eighteenth and nineteenth centuries. Chocolate candies were known in the late 1600s but only became common when large-scale production developed at the end of the nineteenth century. Pastry making (*pâtisserie* in French) became a specialty divorced from sugar-working. Candy-

making also became an industry, helped by glucose (from corn syrup), and cheap penny candies emerged as the most obvious sugar confections.

Special uses of the word “candy,” such as sugar candy, rock candy, and candied fruit, hint at the history of confections. Sugar candy is a hard mass of tiny crystals. It is now seldom made (although fudge is a softer version, and maple candy can be considered a special type). To make rock candy, large sugar crystals are allowed to grow slowly on sticks suspended in syrup. Candied (or crystallized) fruit is preserved by soaking in syrup. Concentration is gradually increased until it is strong enough to prevent decay. This was formerly an important preservation method for fruit, stems, and roots, including medicinal items such as lettuce stems and marshmallow roots. These techniques and other candies such as candy canes and jelly beans were brought to North America by European settlers. They can be traced back through the Middle Ages to traditions of sugar-working transmitted westward from the Byzantine and Islamic worlds.

Modern chemistry shows that early candy recipes exploit special properties of ordinary white crystal sugar (known chemically as sucrose) when boiled as syrup. This skill of sugar-boiling is of fundamental importance to the confectioner. First, the crystals are dissolved in water and brought to the boil. Although water boils at 100°C, sucrose does not melt until it reaches a temperature of around 160°C. As weak syrup boils, it becomes more concentrated, and the temperature rises above 100°C. More water evaporates. This increases the sugar concentration, which raises the temperature further, so that more water boils off and the syrup becomes more

The interior of a confectionery shop showing a confectioner making candied comfits. From Balthasar Schnurr's *Kunst- und Wunderbüchlein* (Frankfurt, 1615). ROUGHWOOD COLLECTION.

## HALLOWEEN

Halloween in North America is celebrated by the custom of “trick or treat,” in which collecting candy plays a vital part. The use of the colors orange and black and the images used on the packaging add to the general theme of witches, ghouls, and pumpkins. The festival of Hallowe'en, or “All Hallows Eve,” has its roots in the Christian celebrations of All Saints and All Souls on November first and second; scholars believe this date was originally a pagan festival of the dead that was taken over by the church. Yellow- and orange-striped candy corn (first devised in the 1880s) recalls the idea of harvest, also important at this time of the year.

In Mexico, the Day of the Dead features a particularly vibrant and lavish selection of human and animal figures and skulls made from hard sugar candy or sugar paste sold at local fairs. These appear to have arisen from a fusion of European techniques of sugar-working, Christianity, and elements of native tradition.

In Europe, Halloween and All Saints have some special associations with candy. In southern Europe, All Saints is remembered as a special time when people visit the graves of relatives, and perhaps eat one special seasonal confection, for instance the Spanish *huesos de santo* (almond candy rolls filled with sweetened egg yolk). One place in which many candies are traditional to this date is Sicily. Here, marzipan fruit, *torrone*, and *cubiata* (the latter two local versions of nut or sesame brittle) are sold in special fairs together with *pupi di cena*—statuettes made of hard sugar candy with gaudy foil decorations. These figures recall a general Renaissance tradition, now mostly forgotten elsewhere to the east of the Atlantic, of decorating banquet tables with sugar models.

In the United Kingdom, toffee was traditionally made around the beginning of November, but All Souls traditions to do with candy or other special foods had almost disappeared by the twentieth century. However, the American trick or treat custom has recently been discovered by British children, and candies aimed specifically at this market now appear in the shops.

concentrated until it is entirely molten sugar. The basis for candy-making lies in cooking the syrup to varying temperatures—relatively low for chewy candies, higher for hard candy. These are measured on a special thermometer or by observed “stages” such as the “ball” test used when making fudge.

The art of confectionery is divided into a number of specialized professions, one of them cake decorating. Cake decorations are mostly sugar or sugar-based, and it takes an expert hand to achieve the fine points of piping and design. This confectioner in Knightsbridge, London, is putting the final touches on a Christmas cake in 1958. © HULTON-DEUTSCH COLLECTION/CORBIS.

Another part of the story of candies lies in the chemical structure of sucrose. This consists of two smaller sugar molecules, glucose and fructose, linked together. Dissolved in syrup, the links between the smaller molecules break, giving a mixture of sucrose, glucose, and fructose in water. The original candy was syrup boiled to a temperature of about 115°C, and then stirred, poured into a mold, and cooled. Stirring encourages the mixture to grain: the glucose and fructose bond again as sucrose, and crystals form, giving a hard texture. This is now used only for a few special items such as some of the figures made for the Mexican Day of the Dead and English Kendal Mint Cake. But the same basic technique gives the solid-yet-melt-in-the-mouth textures of fudge, penuche, New Orleans pralines, peppermint patties, and fondant. In these candies, the industry uses numerous technical devices to control crystal size, giving very small crystals and a creamy texture. Careful control of temperature and “seeding” syrups with preprepared crystals of the desired size are two methods.

Syrups boiled to 154°C and cooled quickly remain transparent and glassy and are the basis of hard, clear candies such as fruit drops and golden barley sugar sticks.

Confectioners knew that acid from fruit juice helped to keep clear candies translucent, and in the nineteenth century, they discovered that newly available ingredients, such as tartaric acid (from grapes) or glucose (in corn syrup) were more reliable. These “doctors” alter the chemistry of the syrup so that the relative proportions of glucose and fructose are unequal, inhibiting graining and encouraging a clear candy. Glucose, used to control texture in most industrially produced candies, is a vital ingredient in modern confectionery. Sugar syrups boiled to high temperatures can also be used for pulling, a method for such favorites as peppermint sticks and candy canes.

A third category of candies, which includes jelly beans, red-hots, and M&Ms, is made by panning in a special revolving drum like a large concrete mixer. This is a low-temperature process, using weak syrups cooked to only a few degrees above 100°C. Nuts (especially almonds), seeds (such as caraway or aniseed), and pellets of chocolate or fruit paste are coated with small amounts of syrup and tumbled until the sugar has dried on their surface. Eventually this builds up in thin layers to make a shell. Jelly beans as now made originated in the late nineteenth century but older recipes used bits of fruit paste. The Italian name for candies such as sugar almonds is *confetti*, and a tradition of throwing handfuls of these during festivities is commemorated in the paper confetti thrown at weddings.

Other ingredients add flavor, color, and texture to candies. Sugar paste is a mixture of confectioner’s sugar and soaked gum arabic or tragacanth. Through the centuries, this was valued for modeling flowers and figures and is still popular for cake decoration. It is also an excellent vehicle for medicines and perfumes. Pastes were made up containing strong drugs such as opium or fragrances such as violet to sweeten the breath. Lifesavers and English Polo Mints echo this tradition, although high pressure is now used to compress the sugar.

Fruit confections often rely on pectin for their jellied texture. Gelatin and plant-derived gums provide alternatives in candies such as gum drops and pastilles. Chewing gum was devised in the late nineteenth century as a sweetened confection based on chicle, an elastic latex derived from a Mexican tree. Foundations for the success of this were laid in the 1890s by a dynamic young salesman named William Wrigley. Flour gives a characteristic chewy toughness to licorice candies, and cornstarch is used in Turkish delight (replacing the wheat-derived starches originally employed).

Almonds are used in many confections. Ground with sugar, they make marzipan. In caramelized sugar, they make brittle, although peanuts have become a more usual base for this candy. Almonds are also combined with sugar that has been boiled with egg whites to make French nougat and its relatives *turron*, *torrone*, and numerous other Mediterranean and Middle Eastern variations. Divinity, a softer version of this, developed in the

southern United States. Egg whites gave the spongy texture to early marshmallow recipes; gum or gelatin are now used.

Milk, butter, and cream provide delicious textures and flavors in caramels, butterscotch, and toffee. The ancestor of these seems to have been taffy, unrefined sugar boiled with butter and then pulled. It was made in both England and North America in the nineteenth century, but the traditions have diverged on opposite sides of the Atlantic. In England, taffy has been forgotten, and modern toffee is brittle, hard, and brown. In America, taffy has developed into soft, multicolored salt-water taffy. Chewy caramels, boiled with milk, probably developed from the taffy tradition in the eastern United States. Milk is also important in confections from other cultures. Thick condensed milk is the *dulce de leche* of Hispanic cultures. Similar preparations provide the basis for many Indian and Bangladeshi confections including fudge-like *barfi* and cake-like *gulab jamun*.

The principal contribution that candies and confections make to the diet is concentrated energy. Consumption of candy is high in North America and Europe. According to the National Confectioner's Association, total U.S. consumption hovered around 7 billion pounds per annum for candy and 3.3 billion pounds for chocolate during the late 1990s. Debates continue over the relationship between confections and health problems such as diabetes and heart disease. The consensus is that too much sugar, whatever the source, is bad for the human body. The relationship of sugar and candy to dental cavities is direct and has been noticed for centuries; a visitor to the court of Elizabeth I in England observed that her teeth were black and attributed it to eating too much sugar.

The complex history of candies and confections has seen them go from being expensive luxuries to something consumed every day by everybody. Much of this is due to cheap sugar and industrial production methods. Despite this, they are still considered treats, valued for decorative qualities as well as their intrinsic sweetness. They retain strong links with celebrations such as weddings, christenings, Christmas, and Easter in many countries.

**CANNIBALISM.** There is certainly no shortage of information on cannibalism. A search at any good library will net twenty to thirty books on the topic, and, at the time this encyclopedia went to press, the World Wide Web contained no fewer than 850 sites. Books on the topic range from popular surveys by Askenasy (1994) to anthropological treatments by Brown and Tuzin (1983), Goldman (1999), and Petrinovich (2000) to anthropological critique by Arens (1979) to postcolonial and literary critique by Barker and others (1998). A superficial examination of post-World War II films lists a variety of both serious and humorous treatments of cannibalism, many of them first-rate (*Fires on the Plain* [Japan, 1959], *Soylent Green* [U.S., 1973], *Survive!* [Mexico, 1976], *Eating Raoul* [U.S., 1982], *Silence of the Lambs* [U.S., 1991], *Delicatessen* [France, 1991], *The Cook, the Thief, His Wife, and Her Lover* [1993/1989, France/Netherlands.], *Alive* [U.S., 1993]). The fact that cannibalism is a powerful taboo in most human societies undeniably contributes to our fascination with tales about organisms eating conspecifics (others of the same species), especially humans.

#### THE GREEKS

The ancient Greeks' fears of cannibalism were reflected in the writings of Homer and others. For example, the Titan god Kronos ate his sons Hades and Poseidon and tried to eat Zeus in the fear that they would supplant him. Zeus, the future leader of the Olympian gods, forced his father to disgorge Hades and Poseidon. In another story, the curse on the House of Atreus was brought about by a deceptive form of endocannibalism. Atreus and Thyestes were brothers. In a series of deceptions, Atreus, having killed his own son without knowing who he was, exacted revenge against his brother, Thyestes, by killing Thyestes' own sons and serving them to him at a feast. A final example is in the tale of Odysseus' return from Troy to Ithaca. He stopped at an island in search of food and stumbled on the cave of Polyphemus, a Cyclops. Odysseus escaped from Polyphemus, but not before the Cyclops had devoured a number of his men.

The practice of human cannibalism is highly variable and can be defined in a number of ways: (1) Endocannibalism is the consumption of deceased individuals who live within the group, such as kin and friends. (This pattern was common in New Guinea as an act of veneration.) (2) Exocannibalism is the consumption of outsiders as an act to gain strength or demonstrate power over the vanquished, who had usually been murdered. (3) Starvation or survival cannibalism is the consumption during actual or perceived starvation. (This is well documented in numerous historical sources.) (4) Gastronomic cannibalism is nonfunerary, nonstarvation cannibalism, that is, routine cannibalism for food. (This is not well documented.) (5) Medicinal cannibalism is the consumption of human tissues such as blood, powdered bone, or dried tissue for medicinal purposes. (6) Sadistic cannibalism is the killing and eating of individuals out of sadistic or psychopathological motives. (There is considerable evidence for this pattern of cannibalism.) In exocannibalism, gastronomic cannibalism, and sadistic cannibalism, the victims are murdered before being eaten; in endocannibalism, starvation cannibalism, and medicinal cannibalism, they are not.

### Cannibalism in Nonhuman Animals

Cannibalism occurs in a wide variety of invertebrate and vertebrate species and includes: infanticide, mating and courtship, competitive encounters, eating the old, and eating eggs. Among nonhuman organisms, cannibalism may be either ecological or social. Ecological factors include a limited food supply or the recovery of reproductive investment when food is scarce for infant survival; social factors include competition for reproductive resources or food resources. A general principle is that older individuals usually consume younger ones or eggs; it is relatively rare for adults to eat other adults. Elgar and Crespi (1992) define cannibalism in nonhuman organ-

isms only in cases where an individual is killed (rather than dying a natural death) before being eaten.

In a comprehensive survey of cannibalism in primates in the wild, Hiraiwa-Hasegawa (1992) observed only five species in this practice: *Cercopithecus ascanius* (redtail monkey), *Papio cynocephalus cynocephalus* (baboon), *Macaca fuscata* (Japanese macaque), *Gorilla gorilla beringei* (mountain gorilla), and *Pan troglodytes* (common chimpanzee). In each episode observed, infants were eaten after being killed, and this custom appeared to serve a nutritional (therefore, ecological rather than social) purpose in animals who ordinarily consumed meat as a part of their diets. Chimpanzees, our closest evolutionary relatives, have the highest rates of cannibalism among nonhuman primates; chimpanzees also have the highest rates of predation (of red colobus monkeys) among nonhuman primates.

### Cannibalism in History and Prehistory

Identification of cannibalism in the distant past is, according to Tim White (1992), based on very specific indicators in fossilized or unfossilized human bones: (1) similar butchering techniques for human and animal remains; (2) similar patterns of long bone breakage (for marrow extraction); (3) identical patterns of processing and discarding after use; and (4) evidence of cooking (White, 1992). Based on these criteria, there is good evidence for cannibalism from the southwestern United States; New Guinea, Fiji, and other sites in the Pacific; and Europe; there is limited evidence at other sites around the world. Ann Gibbons (1997) has reported that very early paleoanthropological specimens dating back hundreds of thousands of years are increasingly being identified as showing signs of cannibalism.

There is abundant evidence from historical accounts of cannibalism in the Caribbean (the term was defined for Carib Indians; the Spanish word *Canibales* is a form of the ethnic name *Carib*) and in Spanish accounts of Mesoamerican ritual sacrifices and cannibalism. Many historical accounts have been challenged within the past few decades because most information was derived from enemies of the groups identified as “cannibals,” where the term was used to denigrate the other group. Also, during periods of exploration from the sixteenth century onward, Europeans were likely to accept the identification of “cannibal” in a group that was thought to be “savage” and “primitive.” Hence, there is probably some exaggeration in the historical literature.

A storm of controversy has arisen over new evidence for cannibalism in Anasazi populations of the southwestern United States from the period between 900 and 1200 C.E. White (1992) and the Turners (1999) have identified skeletal remains from a number of populations that lived in the Four Corners area that show clear signs of persistent and regular cannibalism (White, 1992; Turner and Turner, 1999). The controversy has been fueled by

### JACK AND THE BEANSTALK

This rhyme from “Jack and the Beanstalk” illustrates an example of threatened cannibalism in a children’s story. Numerous nursery rhymes and fairy tales include cannibalism as part of the theme. Another example is “Hansel and Gretel.”

Fe, Fi, Fo, Fum.  
I smell the blood of an Englishman.  
Be he alive or be he dead,  
I’ll grind his bones to make my bread.

the traditional view of these peoples as peaceful and non-violent and the belief that, if cannibalism did exist, it resulted from periodic famine and hunger, which must have commonly struck prehistoric peoples of the arid Southwest. A new image of these peoples, under the purported cultural influence of Mesoamerican traditions of violence from the south, is one of human sacrifice, cannibalism, and social pathology—quite different from the earlier view.

### **Cannibalism and Survival**

Some of the best-documented examples of cannibalism have been based on the conditions that take place during widespread famines and on accounts of shipwrecked, marooned, or stranded groups of people who have gone for long periods without food. Two of the best-documented of many cases are the pioneer Donner party's isolation in the Sierra Nevada Mountains in the fall and winter of 1846–1847, and the crash of the Uruguayan rugby team in the Chilean Andes in October 1972. In these and other well-documented cases, it is unquestionable that the food acquired by means of cannibalism enabled some individuals to survive rather than starving to death.

A more controversial issue is whether regular cannibalism in groups of people makes the difference between inadequate and adequate dietary intake. The Aztecs of Mexico practiced regular ritual sacrifice of captives and consumed the victims. Michael Harner (1977) and Marvin Harris (1977) argued that this food provided a protein-rich source of nutrients to a large Aztec population that was suffering from limited protein intake due to the absence of Native American domestic animals during pre-Hispanic times. This argument has been countered on the grounds that (1) population density was somewhat lower than estimated and (2) protein sources were available from a variety of plant and wild animal food that, when considered together, provided an adequate protein intake for most of the people.

Garn and Block (1970) argued that the meat yield from an average human body (50 kg) would only provide about 4.0 kg of protein, and that this would meet the daily minimum protein requirements of only sixty adults. However, Dornsteich and Morren (1974) presented a more convincing argument for New Guinea cannibalism in several highland populations. They noted that the consumption of human flesh by the Miyanmin people provided between 5 and 10 percent of the daily intake of protein, which was equivalent to or greater than the protein derived from domestic and feral pig consumption. This basic issue seems to relate to the primary motives that people have for consuming human flesh. It is probably not correct to state that some people practice cannibalism solely as a source of food. There are many other human motives for cannibalism. On the other hand, human tissue has the same nutritional value as any other mammalian tissue when it is eaten, whether by a human or nonhuman predator.

### **KURU**

Kuru can be used as an example of how endocannibalism led to a disastrous epidemic of a degenerative encephalopathic disease, the discovery of a whole class of diseases called prion diseases, a Nobel Prize won by D. Carleton Gajdusek, and the beginning of our understanding of mad cow disease, which led to the mass destruction of livestock in the United Kingdom.

A popular account of the early discovery of kuru is given in a book by Michael Howell and Peter Ford (1985). The Fore people, who live in the central highlands of New Guinea and practiced a form of endocannibalism, were reported to have a disease that had a gradual onset (imbalance) but then progressed rapidly to an inability to stand or sit upright, dementia, and a general neurological deterioration that always ended in death. The Fore attributed the lethal disorder to sorcery, but Western officials believed the epidemic had natural causes, perhaps hysteria. Following work by Vincent Zigas, a district medical officer, and Carleton Gajdusek, a young American scientist, it was discovered that endocannibalism, as practiced by the Fore, contributed to the familial transmission of the infectious agent. By handling and consuming the incompletely cooked remains of the kuru victims, especially the highly infectious brain and nervous tissue, members of the family contracted the disease but did not show symptoms until many years later. The first connection with an animal disease was suggested in 1959 when a veterinary scientist suggested that kuru in humans seemed similar to symptoms of a disease called scrapie that was found in sheep. The most recent epidemic of a prion disease is mad cow disease (bovine spongiform encephalopathy), which is a livestock disease that has been transmitted to humans. This is the second example of a livestock prion disease that has somehow been transformed and become infectious in humans (the first is the probable transmission of scrapie to humans in kuru). Finally, the kuru epidemic in the Fore population was brought to a halt when the Australian government outlawed cannibalism in what is now Papua-New Guinea, and the practice slowly began to decline.

### **Cannibalism and Disease**

The Fore tribe of the highlands of Papua New Guinea was investigated at length beginning in 1957 by D. Carleton Gajdusek, who won a Nobel prize in 1976 for his study of the neurological-degenerative disease kuru,

which he determined was caused by human contact with infected human brain tissue. Kuru, Creutzfeldt-Jakob disease, and bovine spongiform encephalopathy are all transmissible spongiform encephalopathies (TSE) and were formerly believed to be caused by a slow virus infection; recent evidence indicates that they are conveyed by proteins called prions. Among the Fore, the principal pattern of contact with infected human tissue was during the mortuary preparation associated with endocannibalistic consumption of dead kin. In 1979 William Arens challenged Gajdusek's explanation for the spread of kuru on the grounds that there were no direct observations of cannibalism in the Fore people.

Whether cannibalism reflects pathological behavior depends on the circumstances of consumption. Starvation cannibalism appears to be tacitly condoned by Western societies, and other societies have sanctioned a variety of exocannibalistic practices. But perhaps the most abhorrent practice is that of sadistic or psychopathological murder and consumption of human tissue. Jeffrey Dahmer is a most recent example. A deranged young man who did not appear to be abnormal, he was arrested in Milwaukee in 1991 for the murder, dismemberment, and partial consumption of seventeen individuals. There are many other examples of such bizarre and pathological behavior in the literature.

**CANNING.** See *Packaging and Canning*.

**CARAMELIZATION.** Caramelization is the familiar browning of sugars through exposure to heat. The most common form of sugar—table sugar or sucrose—is a disaccharide, a combination of two monosaccharides: glucose and fructose. The two sugars can be easily separated using the enzyme invertase, which is essentially what bees do when they make honey from nectar. Fructose caramelizes more readily than glucose, so baked goods made from honey are generally a bit darker than those made with sucrose.

When sugar syrups are heated, they pass through several distinct stages, each having characteristics that are very useful to confectioners. Different sugars reach these stages at varying temperatures. The following table is for sucrose:

Caramelization of sugar begins around 310°F. When it reaches the light caramel stage (at 356°F for sucrose), many complex chemical reactions change simple sugars into a host of different flavoring compounds. Scissions (the breaking of long molecular chains into shorter segments), rearrangements of molecular components, and subsequent reactions between the resulting new compounds all occur in rapid succession. One of the compounds created during caramelization is biacetyl (C<sub>4</sub>H<sub>6</sub>O<sub>2</sub>), which has a warm buttery scent, but there are also traces of as many as one hundred sweet, sour, and bitter compounds. The complexity of the resulting mixture makes the flavor of butterscotch more interesting than the mere sweetness of sugar. Of course, a number of yellow and brown water-soluble polymers are also produced, which accounts for caramel's coloration. These polymers are often used as colorants in commercial food products, from colas to soy sauce, and even in the variety of pumpernickel known as "black bread."

TABLE 1

Stages in the caramelization of sugar		
Stage	Temperature	Characteristics and uses
All water evaporated	212°F	Sugar is melted and impurities rise to the surface.
Small Thread	215°F	No color; cools soft; no flavor change. Used in buttercream frostings.
Large Thread	219°F	No color; cools soft; no flavor change. Used in preserves.
Small Ball	230–240°F	No color; cools semisoft; no flavor change. Used in cream candy fillings, Italian meringue, fondants, fudge, and marshmallows.
Large Ball	246–252°F	No color; cools firm; no flavor change. Used in soft caramels.
Light Crack	264°F	No color; cools firm; no flavor change. Used in taffy.
Hard Crack	300–331°F	No color; cools hard; no flavor change. Used in butterscotch and hard candies.
Extrahard Crack	334°F	Slight color; shatters like glass when cooled; no flavor change. Used in nut brittles and hard candies.
Light Caramel	356°F	Pale amber to golden brown; rich flavor.
Medium Caramel	356–370°F	Golden brown to chestnut brown; rich flavor.
Dark Caramel	370–400°F	Very dark and bitter; smells burned. May be used for coloring, but has little sweetness left.
Black Jack	410°F	Known to Carême as “monkey’s blood.” At this point, the sugar begins to break down to pure carbon.

Many cooks assume that all the browning done in the kitchen is the result of caramelization, and it is common to see recipes that describe the “caramelization” of seared meats. However, that browning is actually the result of another set of chemical processes known, collectively, as the Maillard reaction. Maillard reactions are similar to caramelization, except that they involve the interaction of sugars and proteins—specifically, fructose, lactose, and one form of glucose with the amino acid lysine—at higher temperatures than those at which caramelization occurs. More complex carbohydrates, such as the starches found in flour, will also break down when heated into simpler sugars that can interact with the protein. That is one of the reasons that meats are often dusted with flour or cornstarch before searing. Since the Maillard reaction begins with a greater variety of chemical compounds than is required for caramelization, the resulting chemical complexity is greater. These reactions account for the wonderfully savory browning of baked breads, roasted coffee beans, and some cooked

meats. If one considers the three differing flavor and aroma profiles of beef when raw, boiled, or roasted, the satisfyingly complex flavor produced by the Maillard reactions in the roasted meat is immediately apparent.

Crème caramel, dulce de leche, and similar desserts owe their flavor and color to both caramelization and the Maillard reaction. In the case of flan, the sauce for the custard is actually a thin coating of hard caramelized sugar used to line the mold before the custard is cooked—the caramel dissolves in water expressed from the cooked custard. In crème brûlée, the caramel topping remains crisp because it is browned à la minute under a broiler or small hand-held torch. Soft “caramel” candies are usually milk-based products that are merely flavored with caramel (but not brittle as true caramel would be).

Caramelization and Maillard reactions require temperatures that cannot be reached when water is present (the boiling point of water limits the cooking temperature to 212°F or less). Caramelization starts around 310°F, Maillard reactions even higher. When the sap of maple trees is boiled to make syrup, caramelization takes place even in the presence of water—because, while the average temperature is below 310°F, the temperature where the liquid is in contact with the hot metal of the evaporating pan is high enough for caramelization to occur. Similarly, the surfaces of roasted meats become dehydrated during cooking, allowing Maillard browning to take place while the interior remains moist.

These reactions (along with similar effects caused by enzymatic processes) can sometimes lead to undesirable browning. For example, when fruit preserves are prepared, the bright color of the ripe fruit must be maintained. Ascorbic or citric acids interfere with enzymatic browning, so they are typically added to low-acid fruits. Similarly, sulfur dioxide prevents the low-temperature Maillard reactions that often occur when carbohydrates and amino acids are present in high concentrations. Sultanas, or golden raisins, are merely raisins in which natural browning reactions have been prevented by sulfur dioxide.

**CARBOHYDRATES.** Plants manufacture and store carbohydrates as their main source of energy through photosynthesis. Once consumed, these organic compounds can be digested, absorbed, and metabolized, supplying humans or animals with energy. Carbohydrates provide roughly half of the total caloric intake of the average human diet. These calories may be used immediately for energy metabolism or may be transformed and stored as glycogen or fat to be used as an energy source as demanded. Dietary carbohydrates are comprised of a wide array of compounds ranging from the simple one- or two-unit sugars to the long chain starches, glycogen and cellulose. Carbohydrates can be classified as monosaccharides, di- and oligosaccharides, and polysaccharides.

**TABLE 1**

<b>Carbohydrate classification</b>		
<i>Classification</i>	<i>Number of sugar units**</i>	<i>Examples</i>
Monosaccharides	1	Glucose, galactose, fructose
Disaccharides	2	Sucrose, lactose, maltose
Oligosaccharides	2–10	Includes the disaccharides
Polysaccharides	> 10	Glycogen, starch, cellulose

\*\*A "sugar unit" is one monosaccharide—each unit is not necessarily the same monosaccharide. For example, sucrose consists of one glucose unit and one fructose unit.

Monosaccharides, often referred to as simple sugars, are the simplest form of carbohydrates and are seldom found free in nature. The three that can be absorbed by the human body include glucose, galactose, and fructose. Glucose is the most abundant of the monosaccharides and the most important nutritionally. It is the repeating monosaccharide unit in starch, glycogen, and cellulose, and is found in all edible disaccharides.

Oligosaccharides are short chains of monosaccharide units that are joined by glycosidic bonds. They generally have between two to ten units, with the disaccharides, those chains containing two units, being the most abundant. The most common disaccharides include:

- Sucrose (from table, cane, and beet sugars), consisting of glucose and fructose
- Lactose (from milk sugar), consisting of glucose and galactose
- Maltose (from malt sugar), consisting of two glucose units

Polysaccharides are long chains of monosaccharide units. The major polysaccharides include the digestible forms (glycogen and starch) and nondigestible forms (cellulose, hemicellulose, lignin, pectin, and gums).

Starch is the most common digestible polysaccharide found in plants. It can be found in two forms—amylose and amylopectin. Amylose is a linear, unbranched mole-

cule that is bound solely by  $\alpha$ -1,4 glycosidic bonds. Amylopectin, which makes up the greatest percent of the total starch content, is branched with  $\alpha$ -1,6 bonds at the branch points.

Glycogen is the major storage form of carbohydrates in animals, found primarily in the liver and skeletal muscle. When energy intake exceeds energy expenditure, excess calories from fat, protein, and carbohydrate can be used to form glycogen. It is made up of repeating glucose units and is highly branched. During times of fasting or in between meals, these chains can be broken down to single glucose units and used as an energy source for the body. Although found in animal tissue, animal products do not contain large amounts of glycogen because it is depleted at the time of slaughter due to stress hormones.

Cellulose is the major component of cell walls in plants. Just as starch and glycogen, it too is made up of repeating glucose molecules. However, the glycosidic bonds connecting the units are  $\beta$ -1,4. These bonds are resistant to mammalian digestive enzymes rendering cellulose, and other substances containing these bonds, indigestible. Thus, cellulose is not considered to be a significant source of energy for the body. However, as a fiber, it is important for intestinal bacteria.

Since cellulose is a major part of the plant cell wall, it also encases some of the starch, preventing the digestive enzymes from reaching it and decreasing the digestibility of some raw foods such as potatoes and grains. Cooking causes the granules to swell and also softens and ruptures the cellulose wall, allowing the starch to be digested.

### Dietary Fiber

Fiber can be classified as soluble and insoluble. Soluble fiber, which includes pectin and gums, dissolves in water to form a gel in the digestive tract. This increases the time the food is in the small intestine, thus increasing the chance of nutrients being absorbed. It is believed that soluble fiber plays a role in lowering blood LDL cholesterol. This could be due to the binding and increased excretion of fat and bile acid (a derivative of cholesterol) or other mechanisms not yet understood. Bacteria in the bowel can use fiber as a food source. These bacteria can degrade the fiber and release some components that can then be absorbed and used by the body. The increased nutrition for the bacteria can increase microbial growth, which can then lead to increased stool bulk, with little of the fiber actually found in the stool.

Insoluble fiber, including cellulose, hemicellulose, and lignin (a noncarbohydrate component of the cell wall that is often included as dietary fiber), absorbs water, thereby increasing the bulk and volume of the stool. It helps to speed the movement through the intestinal tract, preventing constipation, and is prescribed in the treatment of irritable bowel syndrome. It has also been shown that insoluble fibers bind fat-soluble carcinogens and re-

## STARCH

Starch from plants makes up about half of our dietary carbohydrates. Starch molecules can aggregate to form granules that differ by size and shape depending on the source of the starch, for example, corn, potato, and manioc. Although there is no difference in the nutritional value between the starches since all cooked starches are broken down in the body into glucose molecules, they do differ by characteristics such as solubility, flavor, and thickening power. Because of these characteristics, starch is often removed from the source to use commercially. For example, the starch can be removed from tubers such as potatoes and manioc (also known as cassava) through a wet milling process, or in the case of manioc, through leaching and drying. The potato starch is often used as a thickener or instead of cornstarch in recipes, while manioc is best known as tapioca.

move them from the gastrointestinal tract, helping to decrease cancer risk.

Refined and processed foods have not only most of the fiber removed, but along with it many of the vitamins, minerals, and phytochemicals (chemicals found in plants believed to contain protective properties) that contribute to the health benefits of whole grain foods. The federal government's Dietary Guidelines for Americans encourage individuals to include whole grain foods in their diet to ensure adequate fiber to promote proper bowel function, as well as to receive other added health benefits.

### Digestion, Absorption, and Transportation

In order for carbohydrates to be absorbed by the intestinal mucosal cells, they must first be converted into monosaccharides. The digestive process begins in the mouth with salivary  $\alpha$ -amylase that partially breaks down starch by hydrolyzing some of the  $\alpha$ -1,4 bonds. However, the digestion that takes place here is of little significance since food remains in the mouth for only a brief period, although this may differ depending on chewing time. The enzyme continues to work for a short time in the stomach until the pH is lowered due to hydrochloric acid that inhibits the enzyme.

TABLE 2

#### Examples of carbohydrate food sources

##### Monosaccharides

Glucose	Fructose	Galactose
Fruit	High-fructose corn syrup	Milk
Vegetables	Honey	Milk products
Honey	Fruit	

##### Disaccharides

Sucrose	Lactose	Maltose
Table sugar	Milk	Beer
Maple sugar	Milk products	Malt liquor
Fruit		
Vegetables		
Honey		

##### Polysaccharides

**Starch** (rye, oats, wheat, rice, potatoes, legumes, cereals, bread)

##### Dietary Fiber

##### Soluble

##### Pectin

Fruits (apples, berries)  
Jams and jellies (additive)

##### Gums

Oats, barley  
Ice cream (additive)  
Legumes

##### Insoluble

##### Cellulose

Whole wheat foods  
Bran  
Leafy vegetables

##### Hemicellulose

Whole grains

##### Lignin

Fruit  
Seeds  
Bran, wheat  
Vegetables

The bulk of carbohydrate digestion occurs in the small intestine by pancreatic  $\alpha$ -amylase. The pH of the small intestines is increased due to the addition of bicarbonate and bile, allowing the enzyme activity to occur. Specific disaccharidases located on the intestinal mucosal cells help to further break down the carbohydrates into the monosaccharides: glucose, fructose, and galactose.

Once the carbohydrates have been broken down, the monosaccharides can be absorbed by the mucosal cells. Glucose and galactose enter by active transport, which requires energy as well as specific receptors and carriers. Fructose is absorbed by facilitated diffusion. Like active transport, facilitated diffusion requires a specific carrier, but instead of needing energy, it relies on the low levels of fructose inside the cell to "pull" the fructose inside. Once transported through the intestinal wall, the monosaccharides enter the blood through the capillaries and are carried to the portal circulation and then to the liver.

### Metabolism of Carbohydrates

The liver is the major site of galactose and fructose metabolism, where they are taken up, converted to glucose derivatives, and either stored as liver glycogen or used for energy immediately when needed. Although glucose is metabolized extensively in the liver, unlike galactose and fructose, it is also passed into the blood supply to be used by other tissues. Tissues like skeletal muscle and adipose tissue depend on insulin for glucose uptake, whereas the brain and liver do not. This dependence on insulin becomes a problem for diabetics who either cannot make insulin

(IDDM) or are resistant to insulin (NIDDM). For individuals left untreated, dietary carbohydrates cause glucose levels to rise, resulting in hyperglycemia, which will lead to serious consequences if steps are not taken to correct it.

Once in the tissues, the fate of glucose depends on the energy demands of the body. Glucose can be metabolized through the glycolysis pathway to pyruvate where it is either converted to lactate or completely oxidized to CO<sub>2</sub>, H<sub>2</sub>O, and energy. Liver and skeletal muscle can convert excess glucose to glycogen through a pathway known as glycogenesis. The glycogen is stored after meals to be used as an energy source when energy demands are higher than intake. At this time the glycogen is broken down into individual glucose units, a process known as glycogenolysis, and the glucose can be metabolized further. Excess carbohydrates also can be used as a substrate for fat synthesis.

Carbohydrates are an essential part of a healthy diet. They provide an easily available energy source, are an important vehicle for micronutrients and phytochemicals, help to maintain adequate blood glucose, and are important in maintaining the integrity and function of the gastrointestinal tract. Table 2 contains examples of foods that contain the various types of carbohydrates.

**CARÊME, MARIE ANTOINE.** Marie Antoine Carême was born into a working class family in Paris in

1784. When he died in 1833, he was recognized as the greatest chef of his time, and his name was familiar to the rich and famous throughout Europe.

Carême's colleagues, and the public at large, first discovered his talents with the publication of *Le Pâtissier royal parisien* in 1815. It was only the third French treatise devoted entirely to French pastry, following *Le Pâtissier françois* (1653) and *La Pâtisserie de santé* (1790). Carême's approach to pastry was innovative in more than one way. Not only did he perfect and diversify the uses of now classic preparations, such as *génoise* and *biscuit* (sponge cakes) or cream puff pastry, but appears to be the first to give recipes for *fromage bavarois* (pastry cream lightened with whipped cream and stiffened with gelatin) and its elegant derivative, the *Charlotte russe*.

In addition to presenting a far greater number of preparations than his predecessors, *Le Pâtissier royal parisien* was also one of the first to include a profusion of engraved plates throughout. Until then, French cookbooks contained very few illustrations, and when they did, they were almost exclusively devoted to table settings, some of which, nevertheless, included instructions for building very elaborate centerpieces for dessert tables. Carême's engravings, on the other hand, were for finished dishes. To the modern eye, they look less like pictures of food than elaborate architectural constructions: temples, helmets, waterfalls, all made of cooked sugar, almond paste, nougatine, and so on, to serve not only as centerpieces, but also as presentation pedestals for his elaborate pâtés and desserts. For Carême, the way food was served was as important as the way it tasted. He criticizes the way his predecessors seasoned and served "mountains of food," and he even attacks the size and shape of the china they employed.

In his great work on cookery, *L'art de la cuisine française au XIXe siècle* (1847), Carême carries his love of extravagant decoration to new heights for savory dishes, as well, standing cutlets and poultry on end and presenting them in a circle, turban style, or sticking whole fish and roasts with a wide array of decorative skewers garnished with truffles, crayfish, and mushrooms. More important, he entirely revamps the art of cookery itself, arguing, among other things, for a cuisine based on "velvety" sauces, rather than the thin, watery sauces favored in the past and for developing a series of basic preparations (brown and white sauces, court-bouillons, force-meats, etc.) that would become the building blocks of classic French cuisine upon which entire families of preparations could be constructed by combining them or changing the main ingredient or a flavoring.

Despite all of his modernism, Carême preferred the monumental *service à la française*—in which all the dishes of a given course were placed on the table at once—to the newly-introduced *service à la russe*, in which they were kept hot in the kitchen, then served sequentially from platters passed by waiters. "Certainly this method of serving is conducive to good eating," he wrote, "but our ser-

Portrait of Marie Antoine Carême, from a nineteenth-century wood engraving. ROUGHWOOD COLLECTION.

vice à la française is more elegant and lavish.” His influence on French cuisine was enormous, and succeeding generations of chefs continued in the paths he had traced. It was not until 1903, when Auguste Escoffier published his *Guide Culinaire*, that Carême’s authority was finally challenged, but his name is revered to this day as a great master whose contributions irrevocably shaped the course of French cuisine.

**CARIBBEAN.** The Caribbean is generally thought to include the Greater and Lesser Antilles in the Caribbean Sea, as well as the mainland French Guiana, Guyana (formerly colonial British Guiana), and Suriname (formerly Dutch Guiana) in South America, and the Central American nation of Belize (formerly British Honduras). It is a geographic nexus between Old and New Worlds, and as such has been global since its inception as a region. Boasting no distinguishable population of direct pre-Columbian descendants apart from a small Carib community in Dominica, its inhabitants are otherwise composed of a highly diverse ethnic and cultural mix of descendants from the Americas, Africa, Europe, and Asia.

Spain was the initial colonizer of the entire Caribbean, but contiguous Spanish settlement in the Caribbean was limited largely to Puerto Rico, the Dominican Republic, and Cuba. Still, one should talk of the Caribbean as a region distinct from Latin America. The Spanish Caribbean islands have been shaped by experiences similar to those of their non-Spanish neighbors. While their cultural connections to Latin America are apparent—in language, culture generally, and perhaps in political philosophy—their Caribbean experience of slavery, plantation agriculture, and the rise of peasantries accord more with the Antilles. It is food (sugar in particular, but also coffee, cocoa, citrus, spices, and bananas), and not language that culturally unifies the Caribbean as a region historically.

Caribbean food, like the people who have come to inhabit the region, is not homogeneous, nor can we accurately talk about an indigenous diet without accounting for the effects of the Columbian conquest of the Americas. There were indigenous American food plants and tobacco, but there were also scores of new cultivars, from Africa, Europe, and Asia, as well as domesticated animals, which played a major role in the constitution of the region after 1492. But these two categories were not, however, isomorphic with the categories of domestically consumed and exported categories of post-conquest Caribbean food products. Instead, there are two categories of Caribbean food that better account for its history as a region. One encompasses those products that are responsible for constituting the region through a transatlantic system of trade. These products shape the way in which the region is defined by European and North American tastes. The other includes products grown as a direct response to the rigidities of this global system through culturally elaborated alternative systems of production, exchange, and consumption.

#### Repopulating the Region: Foundations of Exploration and Imperialism

Before the seventeenth century, the rights of Spain and Portugal to have colonial monopolies were established by several papal decrees issued in the fifteenth century. *Inter Coetera* of Pope Calixte III in 1456 gave Portugal the right to colonize lands “discovered” while circumnavi-

gating Africa on South Asian exploration. Later bulls, for instance *Inter Coeterna II* of Alexander VI in 1493, affirmed Spanish rights to colonization west of the Azores. Colonization rights, as conveyed by God's earthly representative, were in effect divided hemispherically. The 1493 Tordesillas Treaty, for instance, recognized Portuguese colonization rights up to 270 leagues west of the Azores, thus establishing Brazil as Portuguese but the rest of what is now regarded as the Caribbean and Latin America as Spanish (Mudimbe, 1995).

A common denominator in Spanish and Portuguese colonization should be noted. *Rominus Pontifex*, a papal bull of Nicolas V in 1454, is explicit that the central mission of colonization was proselytization. Non-Christians could be dispossessed of their lands under the doctrine of *terra nullius* (no man's land) or even killed for resisting conversion to Christianity. In fact, as Valentin Mudimbe has documented well in his study of these papal instruments, "if [colonial subjects] failed to accept the 'truth' and, politically, to become 'colonized,' it was not only legal but also an act of faith and a religious duty for the colonizers to kill the natives" (Mudimbe, 1995, p. 61). The grounding of New World colonization by the Spanish in such a religious dictum is responsible in part for the violent character of transatlantic contact, both in the Caribbean region and in mainland Latin America. Disease (particularly smallpox), genocide, and enslavement eliminated most of the indigenous populations of the larger settled islands by the end of the sixteenth century. Beginning in the seventeenth century, settlements by other European nations had a similar effect on the smaller

islands of the Lesser Antilles. Today, only the small eastern Caribbean island of Dominica boasts any bona fide "Carib" Indian population, amounting to no more than two thousand persons.

Spanish settlements had been established, mainly on the islands of Hispaniola and Cuba. A production system using Amerindian slave labor was attempted, but after subsequent failures, some slaves were imported from Africa. Still, within seventy-five years, these settlements had become largely peasant-oriented and insular. Spain had turned its attention to the mainland of Latin America, pursuing a policy of resource (particularly gold) extraction. In the early seventeenth century, various European nations began to challenge Spain's monopoly on colonization in the Americas on the grounds that many of the islands claimed by Spain were not, nor had they ever been, occupied by Spain. British, French, Dutch, Danish, and Swedish explorers began to settle the smaller islands of the Lesser Antilles. Though the colonizers differed, there was one common trait on these newly settled lands—the plantation.

### The Sweet Taste of Colonialism

Columbus's inadvertent happening onto the Americas in 1492 is responsible for a shift of Europe's center from thalassic (focused on the Mediterranean Sea) to oceanic (focused particularly on the Atlantic) (Mintz 1991, p. 112). McNeill has noted the impact of this shift on Europe:

The principal historical impact of the American food crops, I suggest, was that they undergirded Europe's rise to world dominion between the eighteenth and

twentieth centuries. No other continent of the Old World profited so greatly. That was because Europe's climate, and especially its comparatively abundant rainfall, fitted the needs of the American food crops better than anywhere else, except China; and in China rice was so productive that the new crops had less to offer than potatoes and maize did in Europe" (McNeill, 1991, p. 52).

The Peruvian potato, for instance, was extraordinarily important to Europe, as it produced four times the caloric intake of rye bread. Potatoes never replaced grain completely: they do not store nearly as well as grain. But the efficient use of acreage is credited with population booms in Germany and Russia and the quick adoption of industry each experienced.

The constitution of an Atlantic epicenter is reflected not merely in the exchange of commodities between the Old and New Worlds. It is defined by the manner in which the demands made by Europe's growing populations were accommodated. Taste is essentially what defined the Caribbean as a region. The Caribbean provided a hospitable climate for the cultivation of sugar cane, particularly on the flatter, drier islands of the Antilles and coastal South America. The Spanish had initially developed sugar cane production in Cuba in the seventeenth century (Ortiz, 1947) but had not taken an interest in the mass production of the product. British colonization in the sixteenth century began to exploit sugar cane production using existing regional techniques, as well as methods learned from the Dutch occupation of Brazilian sugar estates. French interest in sugar production quickly followed and was equally influential by the eighteenth century. What was most significant about sugar was not the growing pancolonial interest in the cultivation of another New World commodity, but its rapid transformation from a luxury item to a sweet, tempting product demanded by a growing European working class: "...as sugar became cheaper and more plentiful, its potency as a symbol of power declined while its potency as a source of profit gradually increased" (Mintz, 1985, p. 95).

Production of sugar in the Caribbean multiplied to keep up with metropolitan demand. The need for a cheap source of physical labor led to the forced relocation of at least five million African slaves to the Caribbean during this same period. Revolts, slave maroonage (flight from plantations followed by the establishment of communities in remote terrains), and other forms of resistance both on the slave ships and in the colonies did little to slow European expansion of the sugar industry. In fact, at the time that Western Europe began to industrialize in the late eighteenth century, the importation of slaves to the Caribbean, particularly to the French colony of Saint-Domingue on the western third of the island of Hispaniola, was at its highest. Saint-Domingue was so valuable a colony to the French that at the Treaty of Paris they ceded their entire claim to Eastern Canada (now Quebec) in exchange for retaining it, Martinique, and

Guadeloupe. During a protracted conflict of 1791 to 1803 in this colony, which in 1804 would be declared the republic of Haiti by revolting slaves, France and England both endured enormous military losses. France lost nineteen generals, including Leclerc, the husband of Napoleon's own sister Pauline, in the conflict. The "unthinkability" of losing the Haitian Revolution helps explain the silence on the subject in West European and American historiography (Trouillot, 1995). It was the profitability of Caribbean sugar colonies that had shaped the military and economic might of Europe generally and of France and England in particular.

Following the loss of Saint-Domingue, France retracted its New World interests, selling its remaining North American claims to the newly formed United States under the Louisiana Purchase in 1803. Britain's interest in sugar cane production declined along with global prices in the late nineteenth century, as beet sugar production proved more profitable. Prior to its contraction, however, the British employed a number of labor management devices aimed at reducing the costs of labor on their plantations. Between the end of apprenticeship in 1838 and 1917, about 500,000 East Indians were brought, mainly as indentured laborers, into the Caribbean (Williams, 1970, p. 348). The cultural influence is particularly strong where the concentrations of Indians were highest, in Trinidad and Guyana. Chinese laborers were brought, particularly to Cuba. Javanese were brought to Surinam, and African indentured servants to the French West Indies as well.

By the mid-nineteenth century, Cuba emerged as the dominant sugar producer in the Americas. Cuban reintegration into sugar production had begun following the British occupation of Havana in 1762 and the concomitant massive importation of slave labor into Cuba by enterprising merchants. Sugar production in Cuba essentially demonstrates an adaptation of the plantation system to a transition from mercantilist to capitalist interests in the New World. American merchant interests in the Cuban sugar industry developed throughout the nineteenth century and serve to explain, in part, American military intervention in the Cuban-Spanish War in 1898.

American military and financial involvement in Cuba thereafter typifies the manner in which foreign tastes shape the Caribbean's definition as an area in the twenty-first century. Rather than merely serving to satiate the European taste for sugar, the region has been used to satisfy new tastes: for sun, sex, and sin. The elimination of tropical diseases from the Caribbean by the early twentieth century, coupled with the devastation of Europe during World War I, made the Caribbean an attractive tourist destination. Casinos, brothels, and beaches were set up specifically to pander to North American and European interests.

A foreign traveler to the Caribbean is likely to come into contact with a broad range of dishes professing to

be authentic in character. Most food produced for tourists reflects the particular tradition of transatlantic shipping from which these contemporary relations emerge: imported goods today compared to the dry provisions of the colonial period; Bacardi, yet another imported rum consumed over locally produced brands. Even the origins of the Daiquirí come from a drink that was consumed on slave ships to prevent scurvy: it was the name of the place where soldiers from the United States first tasted it (Ortiz, 1947, p. 25). As much as Europe's addiction to sugar defined the Caribbean culturally as a region from the seventeenth to the nineteenth centuries, so too does this new addiction affect it today. Even the concept of a Caribbean nation itself must endure the hungers of North American college students on spring breaks, en route to a "Bacardi Nation" that has petitioned for United Nations membership (Cohen, 1998).

### **Biting Back: Local Food Economies**

Perhaps the most contentious debate among contemporary scholars of the Caribbean concerns the origins of the region's cultural influences. Many argue that African cultural influences define the region culturally (Herskovits, 1990; Brathwaite, 1993). Others have suggested the rigidities of the colonial system were so severe as to preclude the survival of any culture (Frazier, 1966). But one thing can be said about the Caribbean over any other region of the world. The Caribbean embodies all of the elements of what we today might call globalization: rapidity and movement of labor and capital; the amalgamation and negotiation of diverse and worldly cultural influences; and integral development of technology and communications. This, however, should not imply that the region is more culturally manufactured than other regions of the world, or that the late establishment of formal national or regional identities (beginning with the failed West Indies Federation from 1958–1962) is reflected in a lack of cultural distinctiveness. A few scholars have correctly noted that the Caribbean is best defined culturally through processes negotiated by its own inhabitants, and not determined by the mere movement of one or another traits from Europe, or Africa or Asia, to the region (Mintz and Price, 1992; Scott, 1991).

Inasmuch as the plantation system sought to define its inserted inhabitants in the Caribbean region as a monolithically defined production matrix, there were responses in the production, exchange, and consumption of food. Plantation owners were required by the late seventeenth century to provide rations to their slaves, but these tended to be inadequate. Slaves responded by establishing their own provision grounds adjacent to the plantations, on which they grew a wide range of products, not only for their own consumption but for sale as well (Mintz, 1978a; Mintz, 1978b; Gaspar, 1991; Mintz, 1995). So important were these provision grounds that some even revolted to keep them. The 1831 abolition of the Sunday market for the barter and exchange of slave-

produced goods in Antigua sparked uprisings and the burning of several plantations (Gaspar, 1991). During the early years of the Haitian Revolution, "the leaders of the rebellion did not ask for an abstractly couched 'freedom.' Rather, their most sweeping demands included three days a week to work on their own gardens and the elimination of the whip" (Trouillot, 1995, p. 103).

Often the surplus of these gardens was sold in slave markets, some reaching off-island destinations. Though the available historical record seems unwilling to acknowledge the fact, slaves were, in a strict sense internationally mobile. Market women ("hucksters" in the Eastern Caribbean, "higglers" in Jamaica, "Madan Sara" in Haiti) would traffic agricultural products both in local markets and to other islands in the region, either individually or through third parties. An eighteenth-century soldier's diary establishes that nonproduce, even manufactured items—including textiles, "syrup beer and a country drink called mawbey" (Aytoun, 1984, p. 28)—are being exchanged in local markets in the small Eastern Caribbean island of Dominica by these market women, and legitimated through the payment of an often hefty fee to their owners. The ability of the market women to meet this fee (rumored to be as much as a dollar and a half a week—an immense sum by the standards of the day) in cash payments suggests that slave markets were significantly broader than the historical record has typically suggested. Dry goods such as rice, wheat flour, beans, corn, and salted meats we know were imported, both from Europe and the United States, except during interruptions caused by the American Revolution. Similarly, a number of agricultural products were being cultivated on provision grounds: "ground provisions" (tubers, including yams, potatoes, dasheen, tannia, eddoes), citrus, bananas and plantains, breadfruit, cassava (the flour of which is used to make farina), and various herbs, used as a spice, for medicinal purposes, and in Obeah, Voudun, and other Afro-Caribbean religious ceremonies, particularly as a poison against slavemasters and in rebellions.

Until emerging national governments established and enforced customs regulations in the 1960s, the regional circulation of agricultural produce and dry provisions remained primarily a locally constituted economy. Ascendant merchants and entrepreneurs following emancipation began to formalize the importation of dry and canned goods in particular. Local agricultural products continue to have symbolic meanings that reflect the historic articulation of ground provision production with the transatlantic plantation system. In islands where certain agricultural products are abundant, it is not uncommon to see surpluses of certain products—bananas and breadfruit are common in the Eastern Caribbean for instance—given away rather than sold. Land, no matter how small in area, has enormous meaning "as a symbol of personhood, prestige, security, and freedom for descendants of former slaves in the face of plantation-engendered land scarcity" (Besson, 1987, p.15). The South Asian and Far

Eastern contemporary cultural and cuisine influences—for instance in the curry dishes, such as the *roti* associated with Trinidad, Guyana, and Jamaica but abundant through the Caribbean—are in fact the result of colonial responses to labor shortages on plantations following emancipation. British emancipation implemented a four-year period of apprenticeship designed to reorient slaves to wage labor. Yet freed slaves continued to demonstrate a stronger desire to work provision grounds.

An interesting case in which the attachment to provision grounds and transatlantic production intersect involves the emergence of the Eastern Caribbean banana economies from the 1950s onward. Bananas, produced mainly in Dominica, St. Lucia, St. Vincent and The Grenadines, and Grenada, were under exclusive license for sale to Britain during this period. Farmers, most of whom were cultivating plots of no more than a few acres, were required to produce exclusively for sale in British supermarkets in exchange for guaranteed markets. Trouillot has noted the reluctance of Dominican banana farmers to diversify their production cycles because of the symbolic qualities that bananas impart: “We can always eat our fig” was the response. While still green, bananas are a starch, and thus an excellent carbohydrate source. Green bananas (or “fig”) are frequently used in local Caribbean cooking, as a porridge, used with other ground provisions in a stew (*bouyon*), or even used in certain festive cooking dishes, for instance in *sankouche* (with salted codfish, Creole, and curry seasonings). Bananas require about nine months to come to fruition, and the comparisons to a child’s gestation period are sometimes invoked in the care of banana plants.

### **Gobbling Globalization and Globalization Gobbled**

Despite an ideological commitment to local produce, and the proactivity of some small-scale producers, Caribbean tastes are hardly defined by some kind of peasant ethic or veneration of local products. Tubers, once key carbohydrates in the Caribbean diet, are declining in importance. And while even the most prototypical of Caribbean dishes have always to some extent been the product of a Creolization (blending) of locally grown products with imported items such as salted codfish, rice, and flour, imported items, particularly canned items, are gaining as status symbols. Former Jamaican Prime Minister Michael Manley once lamented: “How can we build agriculture if our middle class believes it will surely rot if it can’t buy tin mushrooms from abroad?” (Manley, 1988, p. 37). Monetary remittances from Caribbean persons living and working in more lucrative wage employment in Europe, Canada, and the United States has a long tradition in the Caribbean, and has been responsible for infusing cash into these economies. More recently, the remittance of actual packaged food products is becoming more prevalent (Palacio, 1991).

The retention of land, particularly for agricultural purposes, by small-scale producers and plantations alike,

continues to be under threat, not just by hurricanes, agricultural diseases, and declining prices for many agricultural products, but by a growing nonagricultural sector. Plantations have declined in importance through most of the Caribbean during the last century, and, accordingly, many former estates have been sold off. Supplementing one’s wages on a plantation with the maintenance of a provision garden has thus become increasingly difficult. Golf courses, mining expeditions, and hotel development not only acquire or degrade land, but draw Caribbeans into low-paying service-sector wage positions, making them “a stranger in we own land” (Pattullo, 1996). As labor has gradually been drawn out of the agricultural sector, and land for gardens is increasingly abandoned, sold, or not maintained, many Caribbean people have become increasingly reliant on wages in a highly volatile and unstable service sector to buy these packaged, imported food items.

Local cuisine in some ways has become increasingly foreignized, not merely by the inclusion of foreign products in Caribbean diets, which has always occurred in varying degrees, but through substantial changes in the ways in which Caribbean fare is internationally recognized. Foreign investment interests increasingly appropriate local cuisine for commercial purposes. Hotels throughout the Caribbean are notorious for hiring European chefs to cook “authentic” Caribbean dishes, which are often flashy reinterpretations or fusions of Caribbean fare—*accras* (fried codfish) are marked up as much as ten times in price in foreign owned restaurants for the mere addition of tartar sauce. And the local dishes historically consumed by Caribbean people are likewise affected by these changes. Fried chicken is now ubiquitous, so much so that Kentucky Fried Chicken is the only franchise on many of the more sparsely populated islands. The longest lines in any Caribbean capital will be at the fast-food chains. Locally, Ovaltine has far more cachet than the Blue Mountain Coffee of Jamaica sought by upper-class American consumers. And apart from national celebrations in which folk recipes predominate, most celebrations throughout the Caribbean are overcome by, as some complain, “rum and coke and smoke,” the smoke being from the barbecue.

Despite the dramatic changes to Caribbean food through the postwar period of modernization and international development, local responses to these changes continue to be informed by an ongoing process of Creolization. Foreign phenomena continue to be incorporated into local dishes. *Pealeu* (a specifically Creole dish, but ostensibly the same rice and beans-based dish found throughout the Caribbean) was once regarded in the Eastern Caribbean as a dish that usually included fish. Declining fishery production and the rapid growth of frozen chicken imports have changed the content but not the underlying Caribbean form. Caribbean food has established its distinctiveness historically by creatively and strategically incorporating diverse elements into a

localized answer to the rigidities imposed by foreign consumer demands.

**CASSAVA.** Cassava, or manioc (*Manihot esculenta*), is a root crop native to tropical America that is now consumed by millions of people throughout the tropics, and is used in food preparation in many industrialized processes. Although it is not well known outside the tropics, cassava now accounts for about 30 percent of the world production of roots and tubers. It is an exceptional producer of carbohydrates and a plant better able to tolerate seasonal drought than other major food crops.

#### Plant Biology

The cassava plant is a perennial woody shrub that grows from about one to three meters in height. The leaves are palmate (hand-shaped) and dark green in color. The cone-shaped roots are starch storage organs covered with a papery bark and a pink to white cortex. The flesh ranges from bright white to soft yellow. Over five thousand varieties of cassava are known, each of which has its own distinctive qualities and is adapted to different environmental conditions.

The cassava plant is hardy and better able to tolerate drought and poor soil conditions than most other food plants. It can grow in extremely poor, acidic soils because it forms a symbiotic association with soil fungi (mycorrhizae). It is also one of the most productive food plants in terms of carbohydrate production per unit of land, and unequalled in its ability to recover when foliage is lost or damaged by diseases or pests.

The cassava plant is somewhat unusual, and even infamous, because both the roots and leaves can be toxic to consume. The toxicity of cassava is due to the presence of cyanogenic glucosides (compounds of cyanide and glucose) which liberate hydrogen cyanide (HCN), a potent toxin, when the plant tissue is damaged. Cyanogenic glucosides are found throughout the plant and in all varieties of cassava. Varieties referred to as “sweet,” or low-cyanide, have low levels of cyanogenic glucosides in the flesh of the root and can be peeled and cooked like other root vegetables. Those referred to as “bitter,” or high-cyanide, have higher levels of cyanogenic glucosides throughout the root (peel and flesh) and require more extensive processing before they are safe to consume. A number of different processing techniques are used (grating, fermenting, sun drying), all of which serve to damage the plant tissue and hence cause the liberation and volatilization of HCN. The potential toxicity of cassava foods depends on the effectiveness of processing and preparation techniques; high-cyanide roots can be processed to remove all most all traces of cyanide-containing compounds. Many farmers prefer to cultivate the high-cyanide varieties for reasons that are not entirely clear.

## History

Cassava was domesticated sometime in the distant past, maybe five thousand years ago. Exactly where is not known, but the current consensus is that domestication took place somewhere in Central or South America, perhaps along the southern border of Brazil, where wild relatives of cassava are currently found.

Cassava was the staple crop of the Amerindians of South America when the Portuguese arrived in 1500 just south of what is known as Bahia, Brazil. The Amerindians living in the area were the Tupinamba, who relied on cassava as a dietary staple, processing it into bread and meal using techniques similar to those still used by Amerindians in the twenty-first century.

When the Portuguese began to import slaves from Africa in about 1550, they used cassava in the form of meal (*farinha*) to provision their ships and began cultivating cassava at their stations along the coast of West Africa soon afterward. From their stations near the mouth of the Congo River, cassava diffused to all of central Africa. The Portuguese were also responsible for introducing cassava to East Africa, Madagascar, India, Ceylon, Malaya, and Indonesia by the 1700s.

Cassava was probably first introduced into Asia during Spanish occupation of the Philippines and was distributed throughout tropical Asia by the beginning of the nineteenth century. Expansion of cassava cultivation was pushed by colonial administrators who saw cassava as a famine reserve (especially the Dutch in Java, and the British in India), and as an export commodity (Malaya and Java in the 1850s).

## Procurement and Production

Cassava is typically grown by small-scale farmers using traditional methods, and farming on marginal lands not well suited to other crops. It is propagated by planting stakes cut from the woody stems of mature plants. These plantings require adequate moisture during the first two to three months, but after that they are relatively drought resistant. Cassava roots mature to harvestable size in six to twelve months depending on variety and ecological conditions, and can be harvested at any time in the following two years, a harvest window that provides farmers an unusual degree of flexibility. To harvest the plants, farmers typically cut off the top three-quarters of the plant, and then pull up the roots and separate them from one another. Mechanical harvesting is still relatively rare.

Because fresh cassava roots deteriorate rapidly (within three to four days) after harvesting, they are usually consumed immediately or processed into a form that has better storage characteristics. Fresh roots (low-cyanide) destined for distant markets can be sealed in wax, packaged in plastic bags, or frozen to prevent deterioration. Leaves can be harvested at any stage of the growth of the plant, but typically only the youngest leaves are picked. The leaves deteriorate rapidly after harvesting and so are generally cooked the same day.

## Cassava Foods

Cassava roots are prepared into an amazing variety of foods. Traditional preparation techniques vary by region, and by ethnic group within a given region.

**South America.** For Amerindians, the most common ways of preparing high-cyanide cassava were as a bread (*casabe*, *cazabe*, *beiju*), a roasted granular meal (*farinha*, *farinha*), and as a beer (*chicha*). In the northwest Amazon the bread is a large, thick (one inch or more) flat bread made by peeling and grating the roots, and then sieving the grated mash with water to separate the liquids and starch from the more fibrous portion. The starch is allowed to settle, and the liquids decanted off the top, then boiled to make a drink (*manicuera*). The starch and fibrous portion of the roots are stored separately and allowed to ferment for forty-eight hours before being dewatered, and then recombined and baked on a large clay griddle. In Venezuela and Guyana the bread is a thinner, hardtack-like bread made without the starch extraction step.

*Farinha* is made by soaking the roots of yellow-fleshed, high-cyanide varieties in water until they ferment. The roots are then peeled, grated, mixed with fresh grated roots and the mixture allowed to ferment for a week or more. The mash is then dewatered, sprinkled onto a hot griddle, and roasted while being stirred. The resulting product is a dry granular meal that can be stored almost indefinitely. It is most commonly consumed as *chive*, a drink that is made by putting a handful of meal in water and swirling to mix. Well-made meal can expand five times in volume and results in a full feeling.

Cassava bread being baked on a stone griddle at Dritabiki, Suriname. The bread, which is drying in the sun in the foreground, is paper-thin and brittle when eaten. Among the Djuka peoples of Suriname, the bread is crumbled to make a dried cereal called *kwak*. © ADAM WOOLFIT/CORBIS.

*Chicha*, a mildly alcoholic beer, is made from both low-cyanide and high-cyanide cassava. With low-cyanide varieties it is prepared by peeling, cooking, and mashing the roots, then adding water and some masticated roots and allowing the mixture to ferment. With high-cyanide varieties it is prepared from *manicuera* (the cooked juices) and a very thin bread, some of which is masticated, and other cooked roots or tubers.

In the national cuisines of South America, low-cyanide cassava is used as a vegetable (boiled, or boiled and fried). In Brazil, *farinha* is part of a number of traditional dishes, and in Colombia several breads are made with the fermented starch of high-cyanide cassava.

**Africa.** Cassava is the second most important food crop in sub-Saharan Africa. The majority of the cassava-based foods made in Africa rely on fermentation in one form or another. Two common products are *gari*, a granular meal similar to *farinha*, and *fufu*, a sticky dough made by

pounding cooked or fermented roots into a paste. Other products include *chikwange* or *baton de manioc*, a steamed/boiled paste made from soaked roots, and *lafun*, a flour made from soaked roots.

**Asia.** Cassava roots are prepared in most Asian countries by boiling, baking, and frying. Another widespread practice is to peel, slice, and sun dry the roots and then grind them into a flour. The flour is then used to make porridge, or other traditional foods like *chappatis* and *dosas* (India), *bibingka* (Philippines), and a rice-like product called *landong* (Philippines). Commercially produced cassava starch is exported as tapioca.

**South Pacific.** Boiling and baking are the most common techniques for preparing cassava roots. On some islands cassava is also used to prepare *ma*, a traditional fermented product typically made from breadfruit.

**North America and Europe.** The pure starch, or tapioca, extracted from cassava roots is commercially available as a flour, flakes, or pellets (pearls) and is used to thicken a wide variety of food products such as sauces, gravies, pie fillings, pudding, and baby foods. The well-known dessert tapioca pudding is made with the pearls, which become gelatinous, semi-transparent balls in the finished product, affectionately referred to as “frog spawn” by British schoolchildren.

### Relations to Human Biology

Fresh peeled cassava roots are rich in carbohydrate (30–35 percent), and low in protein (1–2 percent) and fat (less than 1 percent). They have nutritionally significant amounts of calcium (50 mg/100g), phosphorous (40 mg/100g) and vitamin C (25 mg/100g). The quality of the protein is relatively good, and the starch is highly digestible. Fresh cassava leaves are a good source of protein (23 percent), vitamins, and minerals.

The cyanide-generating potential of cassava roots and leaves has been of considerable concern. Although traditional methods of processing are effective in reducing cyanide content to innocuous levels, inadequate processing, as sometimes occurs during famine and periods of social upheaval, or the rush to market, can lead to health problems, particularly cyanide poisoning.

In South America there is no evidence of acute or chronic cyanide toxicity associated with cassava consumption by Amerindians for whom cassava is a traditional dietary staple, even though some groups rely on varieties of cassava with a very high cyanide content. In other parts of the world, however, cassava consumption has been associated with cyanide toxicity and other disorders. Acute cyanide poisonings are relatively rare, but can be fatal. The cases typically involve the consumption of raw or inadequately processed cassava. The symptoms are dizziness, headache, nausea, vomiting, and diarrhea.

In Africa, cassava-based diets have been associated with two neurological disorders: tropical ataxic neuropathy

thy (TAN) and konzo. Both occur among the rural poor on diets largely restricted to high-cyanide cassava. TAN is a disease characterized by ataxia (muscular incoordination), reduced sensory perception, and deafness. The onset is slow and the course progressive, and it is found primarily in adults over the age of forty. Konzo is a disease characterized by the sudden onset of spastic paralysis in both legs, which results in a slightly spastic gait in mild cases and a complete inability to walk in severe cases. It primarily affects children and women under forty, and tends to occur in areas under conditions of famine or near-famine when people have nothing to eat but cassava and their nutritional status is poor. Both of these disorders are relatively rare given the millions of people on cassava-based diets in Africa.

The cyanide found in cassava-based diets is metabolically detoxified to thiocyanate and therefore cassava consumers have higher than normal levels of thiocyanate in body fluids. This is thought to be beneficial in areas of West Africa where sickle-cell anemia is present because thiocyanate inhibits the tendency of hemoglobin molecules to sickle. It is problematic in areas of Africa where the dietary iodine intake is low because thiocyanate blocks iodine uptake by the thyroid gland. In these areas, cassava consumption is associated with iodine deficiency disorders including goiter, cretinism, mild mental disorders, and other related conditions.

### Cassava as a Symbol of Identity

Important food plants like cassava tend to be powerful symbols of social and cultural identity. These symbolic associations can be clearly seen in South America.

For the native people like the Tukanoan, cassava is one of the most important and highly valued foods, and is consumed with meals and most snacks. They believe that cassava was the first food; it was planted by the first woman to make bread for the first man. They consider the extracted starch, *weta*, to be the purest, whitest, and more nourishing of foods. The term *weta* also means the essence of something. For non-Indian subsistence farmers in the Amazon, farinha is an essential component of everyday meals and snacks, as well as an ingredient in special dishes. People will go to considerable trouble and expense to obtain it from the market when home-produced supplies run out because cassava is part of the fabric of everyday life, and consuming it part of their identity. In contrast, for Brazil's urban elite, farinha is only occasionally consumed as part of certain traditional dishes, and the everyday consumption of farinha is seen as a marker of lower class status and poverty.

### Global and Contemporary

Cassava now provides about 30 percent of worldwide production of roots and tubers, and is the staple crop of over 200 million people in Africa alone. World production increased more than four-fold in the last two decades of the twentieth century, with most of this increase being

in Africa. Cassava is a crop with enormous potential to provide food energy, and a crop that will play a particularly important role in areas like Africa where the production of adequate food is a serious challenge.

It is also a crop that has received relatively little attention from researchers in comparison to the dominant food crops of the green revolution—wheat, rice, and maize. However, efforts are underway to rectify the situation, and find ways to capitalize on cassava's strengths (high productivity, tolerance of poor soils and low rainfall, and relatively good resistance to pests and disease) and to improve its major shortcomings (rapid postharvest deterioration), and address its cyanide content. The following areas are particularly promising:

1. The use of microbial biotechnologies (technologies that utilize organisms like fungi and bacteria) to improve production and the processing of traditional products and to develop new products. Cassava production depends on soil mycorrhiza (fungi), and processing technologies depend on a variety of fungi (*Aspergillus*, *Saccharomyces*, and others), and bacteria (mostly *Lactobacillus* and *Corynebacterium*) to reduce toxicity, improve storage qualities, and achieve the desired taste and texture of cassava foods.
2. The use of micropagation (culturing of tiny masses of dividing cells) for the exchange of varieties. This is particularly important for cassava because the plant is traditionally propagated from vegetative stakes that can transmit disease.
3. The use of genetic biotechnology for inserting new genetic material (DNA) into cassava varieties in order to improve quality and disease resistance.

**CATTLE.** The history of the domestication of cattle, their use as key elements of human survival systems, their biology, how and when they are currently raised, and how they are processed and marketed for consumption are all issues that help us understand beef as a part of different food systems. "Cattle" refers to live animals, including the young (calves), females before giving birth (heifers), females that have given birth (cows), fertile males (bulls), and castrated males (steers). Beef is the meat of all these animals while specialized terms for beef, such as veal (the

meat of young, milk-fed calves), relate to food preferences in different cultures.

Beef is produced and consumed worldwide, and, like that of many commodities, its production is increasing. It is consumed not only as hamburgers, roasts, and steaks, but meat by-products including hides, horns, hoofs, intestines, and brains are used in a variety of products including: shampoo, marshmallows, ice cream, gelatin, cement, chalk, chewing gum, makeup, matches, margarine, and strings for musical instruments and tennis racquets. Beef is raised in three phases before it is processed: calves are raised on pasture and range land, as feeder cattle they feed on pasture, crop residue, and range land, and finally they go to feedlots, where they are fattened for slaughter. The slaughterhouse (packer) is also the disassembly plant, where the carcass is divided into "cuts." Since the advent of boxed beef, most of the disassembly occurs at the plant itself, whereas previously sides of beef went to wholesale or retail butchers who divided it further. After slaughter, the commodity chain diverges. A portion goes directly to wholesalers, who distribute to institutional users or grocery stores, although grocery chains are increasingly linked directly to the packer. Another portion goes into further processing for sausages, bologna, hot dogs, and other processed meats, or is used for canned and frozen "heat and eat" meals. The carcass is rendered and the by-products are used in a wide variety of products. For example, hooves can be made into gelatin, hides into leather, bones and cartilage into bonemeal for plant nutrition, and intestines and some organs and other parts not usually used in meat markets go to pet food. Up until the mid-1980s, the

bones and nerves were ground into bone meal and fed as a supplement to cattle and other animals, until this practice was banned. Beef is increasingly consumed in restaurants, from steakhouses to fast food establishments. There is enormous variety in the use of all parts of the animal for delicacies prepared for home use and street food sale, from the stomach (tripe soup in many cultures) to the tail. Lower-quality beef and inferior parts are used in Japan in a simple dish called *nimono* as a kind of seasoning.

Biology

**Description.** Cattle are large ruminants of the family Bovidae and the genus *Bos*. Ruminants are mammals whose stomach has four parts—rumen, reticulum, omasum, and abomasums. The rumen provides a pouch where fibrous plant materials are broken down by bacteria so their nutrients can be digested. Because they are ruminants, cattle can digest plant materials that serve no other human use. As herbivores, they are selective eaters, but consume a variety of types of plants.

From the time of their original domestication, cattle were selectively chosen to meet multiple human needs, including providing traction and transportation, meat, and milk. Cattle have provided fuel for cooking and heating, plaster for walls, manure for gardens and fields, strings for musical instruments, and clothing—from hats to shoes. Originally valued for docility, cattle are increasingly bred to meet specific needs of those who raise them, process them, and eat them.

The systematic development of cattle breeding began as a part of the industrial revolution and the renaissance of British agriculture. The enclosure movement in England in the sixteenth century not only forced rural peasant farmers from the land to work in factories, but left privatized lands in the hands of a few landed gentry who could breed the stock they desired. Breed formation started with a useful local type that was then inbred until it showed uniformity. Breeds were then shown at livestock fairs that were part of the country lifestyle of the landed classes. Heredity was carefully recorded in herd books, and sires and mating were carefully controlled. Pure breed associations were formed. It was in this context, between 1750 and 1850, that the Angus, Hereford, and Shorthorn breeds were developed.

In other regions of Europe, inbreeding had produced uniform and locally adapted breeds, although specialization in rearing and feeding cattle for beef occurred long after it had in Great Britain. In the United States, interest in breeding began around the turn of the twentieth century (numbers had been important up to that point). In particular, Herefords were imported because they matured early, which allowed for the slaughter of yearlings rather than the four-year-olds prevalent at that time. In parts of France, five- to six-year-olds are still preferred for their flavor, particularly if they are fattened on grass.

In the course of seeking early maturing animals, many lines and traits have been lost. However, the introduction of new breeds has transformed the appearance—and probably the taste, nutritional qualities, and tenderness—of cattle in beef-exporting nations, particularly the United States and Canada.

**Original extent.** Cattle may have originated at about the same time in Europe, Asia, and Africa. Surviving relatives are present on all three continents. Seldom kept solely for beef production, cattle were beasts of burden as well as critical providers of milk and butter. They were only slaughtered when their ability to produce these ongoing products was reduced, at which point their hides, hooves, horns, bones, intestines, and other non-edible parts were valued as much as their meat, which generally supplemented that provided by wild game. Modern domestic cattle are believed to descend from *Bos taurus*, which includes European breeds such as Shorthorn and Jersey and *Bos indicus*, which includes Zebu breeds from South Asia and Africa. Cattle in much of the world were primarily used for traction for crop agriculture and for transportation.

**Nutritional and nonnutritional constituents.** Bovine flesh is called beef when the animal is mature and referred to as veal when it is a calf. Beef provides high levels of energy and protein. Proteins found in beef have a higher digestibility than most plant proteins and a wider range of amino acids. The bioavailability of important minerals (including calcium, phosphorous, iron, zinc, magnesium, and manganese) as well as vitamins (including thiamine, riboflavin, niacin, pyridoxine [B6], and B12) is high in beef. In many parts of the world, beef is viewed as the most fortified and most nutritious butcher's meat. High in iron, it can also be high in cholesterol and highly saturated fatty acids, as for many years cattle were bred for weight gain. Corn-fed cattle have higher levels of omega-6, which is a coagulant, in their meat. Grass-fed animals, in contrast, have much higher concentrations of omega-

TABLE 1

Characteristic	<i>Bos taurus</i>	<i>Bos indicus</i>
Ears	Short and erect	Long and drooping
Hump	Absent	Well-developed and fleshy
Skin	Relatively tight	Very loose
Hair	Long and thick	Fine and short
Horns	Short and turned down or hornless	Long and turned up
Call	Bellow	Grunt
Body	Wide through barrel and hindquarter	Narrower throughout
Temperament	Relatively docile	Nervous
Heat tolerance	Poor	Good
Birth weight	High	Low

These distinguishing characteristics have been combined and recombined in over a hundred different registered breeds.

3 fatty acids, which have anti-inflammatory properties and are anticoagulants. Too much omega-6 leads to clogged arteries, while omega-3 fatty acids do not. Fat content in general depends on the cut of beef, genetics, and the feeding of the animal prior to slaughter.

## History

**Domestication.** Among early transhumant populations, which moved seasonally to find food, herds of hoofed mammals that were the ancestors of our current breeds moved with them. Initially roaming to find grass as seasons changed, cattle were later driven to provide a constant source of fuel and milk. As human life became more sedentary, cattle were an important part of the move to agriculture, providing traction for plowing in many sites in the Old World. In the New World, cattle were introduced with European colonization.

**Historical diffusion and trade.** Cattle husbandry was a part of Roman culture and spread with the Roman Empire. Norman conquerors brought beef-eating to the British Isles, although cattle were already serving many other functions for farm households. Cattle culture was an early part of complex social organization, often representing wealth. For example, the Celts based their wealth on cattle prior to 1066. In fact, in a number of languages the root word for cattle and for money is the same. In parts of Africa, wealth is judged by number of cattle, and dowries are paid in cattle.

South American grasslands did not have large ruminants before the Spanish and Portuguese introduced cattle to the grasslands from Argentina and Chile to Mexico and the southern part of what is now the United States. Raised on large *estancias*, *fazendas*, or *haciendas*, they were valued primarily for their hides, hooves, and horns, which could be exported to Europe. The owners of the large estates employed *vaqueros*, *gauchos*, or cowboys to undertake the day-to-day care of the cattle and to drive them to the appropriate place for shipping or slaughter. Thus, cattle imported to the New World from Spain were primarily beef cattle, the famous long-horns, tough for eating but resilient, and able to utilize the meager feed available in the dry plains of the central North American continent.

Australia and New Zealand grasslands were the last to have cattle introduced. The first cattle, black Africaner, arrived in 1788 and Zebu cattle arrived from India in 1795, followed by English breeds. While settlers introduced cattle, it was large companies that exploited the great potential of the early cattle industry in Australia. The early cattle were driven to follow forage and water availability and then to slaughter. Wire fencing in the 1860s and bore wells and the railway boom in the 1880s allowed for the establishment of permanent cattle stations. With the first shipment of frozen beef to England in 1879, the cattle industry became export-oriented.

Europeans who came to the North American continent and the Antipodes (New Zealand and Australia) brought their livestock with them. There was much genetic diversity in the livestock that arrived with migrants from different rural areas of Europe. The cattle from northern Europe tended to be triple-purpose cattle—for traction, milk, and meat—and they tended to be either family cows or small herds of beef raised on family farms outside population settlements.

The coming of the railroad transformed cattle production in North and South America, allowing both livestock and sides of beef to travel further faster. Beef was produced primarily in the plain states. Cattle drives to railheads gave rise to the myths of the cowboy. Railroads transported the cattle to population centers, where they could be butchered nearer to the consumer. The wide dispersal of cattle and their seasonal migrations was gradually cut back as the plains were fenced and other forms of agriculture competed with cattle for the land.

Yet even in the east, the ability of ruminants to convert plant materials of all kinds into food meant that land unfit for agriculture, because it was too steep or too poorly drained, was used for grazing cattle. As farmers moved into the plains in the 1830s and 1840s, before the lands of the majority of states like Iowa and Illinois were drained for agriculture, cattle were an important part of the farming mix using land that was unfit for cultivation or homesites. As soil was drained, however, less land was used for pasture, and more was used for crops.

Cattle were still the cheapest way of shipping the course grains, particularly corn. Meadows changed to pasture, and then were drained and became cropland. The farmers who moved to these reclaimed areas were almost all commercial rather than subsistence. As cities grew, the demand for meat increased.

James Whitaker argues that “through a combination of availability of railroads, type of land tenure, cost of drainage, and price of beef in the 1880s and early 1890s,” many of the states shifted to producing cash grains rather than fat cattle (1975, p. 14). Mechanization in particular helped bring about this change, as did the ability to open up the prairie with chisel plows.

During the nineteenth century, cow/calf operations and fattening cattle were further differentiated. By 1819, cattle feeders from Indiana, Ohio, and Kentucky were traveling as far west as Missouri and Oklahoma in search of young animals to take home for fattening on corn in preparation for the overland drive to the eastern markets. But some cattle producers believed they could raise cattle and corn more cheaply in Iowa and Illinois than in Ohio or Kentucky. Those cattle were driven to eastern markets or shipped south to New Orleans on the Mississippi.

Those who first drove feeder cattle east to fatten brought the cattle-feeding pattern to Iowa and Illinois when they returned to settle after seeing the advantages

In some cultures, cattle were far more valuable as draught animals than as food. © ARCHIVO ICONOGRAFICO, S.A./CORBIS.

of cheap prairie grass and corn. Until the Civil War, these cattle went primarily to the eastern markets.

Farmers had to go greater distances to find the feeder cattle they needed to fatten for market. Cow/calf operations, which thrived on smaller farm units, encouraged settlement. Large-scale operators gathered their herds from farmers who felt that feeding cattle was not profitable with less than two dozen head (Whitaker, 1975, p. 22). Thus, small operators produced the calves, while larger operations fed them out and fattened them.

After the Civil War, feeders again returned to Texas and the plains. The increasing use of the western range as a source of feeder cattle brought significant changes to the cattle feeding industry in the Corn Belt. There were two available feeding strategies: 1) purchase cheap western cattle, feed them for a year, and then sell for a small profit margin per animal hoping to make money on the large volume of sales; or 2) pursue a low-volume business of better quality of cattle bringing a larger profit per head. Improved cattle provided a way to get the most profit out of good grass and good corn while not robbing the land of its fertility as the cattle recycled the nutrients they consumed.

Those who followed the second strategy were more interested in improved beef breeds. Farmers were slow to improve their herds, but those who did generally profited from it. Because cow/calf operations were a small part of many farms, breed and pasture improvements were not quickly or widely adopted.

By the end of the 1850s, cattle were being fattened in Iowa and Illinois rather than being calved and weaned and driven east to be fattened. In the years after 1865, technological advances contributed to the continued growth and expansion in the beef industry. Illinois and Iowa became leading producers of corn-fattened cattle and Chicago became one of the world's leading cattle markets. The organization and expansion of a central market in Chicago was a result of the new railroad network, the concentration of meat packers in Chicago, the development of refrigeration facilities, the reorganization of retail meat marketing, and growth of the export trade in live and dressed beef. Demand for dressed beef increased, and the Corn Belt states met that demand with the combined production of cattle and corn.

The Civil War and the railroads brought centralization of market facilities, as increased receipts of livestock created chaos in handling transactions between several markets in the city. Formation of the Union Stockyards in 1865 was critical to bringing order out of chaos and in concentrating power. Demands of the new end market, created by the expansion of the railroads, gave rise to the dressed beef industry and the major packers who controlled it.

Although the technology existed before the Civil War, it was only in the late 1860s that refrigeration was effectively used to prevent the early spoilage of fresh meat, lengthening the time and distance from point of slaughter that fresh beef could be consumed. At first,

consumers distrusted the quality of meat shipped hundreds of miles after being slaughtered; but, because dressed beef was sufficiently cheaper than local butcher stock, people were willing to try it.

The Swift Company was critical in moving this conversation forward. Swift and other companies fought with the railroad about whether dressed beef could be shipped at the same rate as live cattle. The invention of the hermetically sealed tin meant that corn-fattened cattle from Illinois and Iowa could be packed and shipped to domestic and foreign markets.

Soon after the Civil War, in the early 1870s, Chicago packers replaced packing pickled beef in barrels with canning. A court ruling that invalidated patented claims on the canning process triggered the expansion of canned meat. Western beef tended to be canned, as the quality was inferior to the corn-fed beef of the Midwest.

The great expansion of the market through technological and marketing changes in the dress beef trade created large vertically organized Chicago-based corporations. These corporations controlled, for the most part, both the wholesale and retail domestic markets for beef products. Known as the “big five,” Armour & Company, Patrick Cudahy, Nelson Morris, Swift & Company, and Wilson & Company frequently acted together in buying cattle in the Union Stockyards and dividing retail trade among themselves. They also set prices and attempted to eliminate some of the less profitable aspects of competition.

As these companies were expanding rapidly due to the sharp increase in demand, they were pressed for cash and, thus, worked hard to lower both the price of labor in the packing plants and the cattle they purchased. To compound the problem of vertical integration and monopoly, a number of the packers went into the cattle feeding business.

By 1900 the concentration, if not the ownership of packing plants, had become decentralized. The major leading packing centers, with the same packers owning most of the capacity, were located in Chicago, Kansas City, Omaha, East St. Louis, and St. Joseph. There were lesser centers in Des Moines, Sioux City, St. Paul, and Fort Worth. The packers had so revolutionized the meat trade that butchers in some circles in the 1920s claimed that “not a retail butcher has made a fair profit and a living in the last ten years” because of packer branch houses (Whitaker, 1975, p. 54).

A major transformation of beef packing, which had previously been located near consumers and the transportation centers of larger cities, occurred with the founding of Iowa Beef Packing in Denison, Iowa, later renamed IBP. To lower buying costs, shorten transportation distances, and eliminate intermediaries, IBP put its plants near large feed lots, which tended to be located near sources of feed grains and away from large population centers.

Work on the plant floor was organized to require less skilled and less experienced workers. Thus wages could be considerably lower than in Chicago, Kansas City, or even Des Moines. Focusing on primal cuts, they became known as “kill and chill” plants, shipping to meat processors all the specialty items that were once part of traditional packing plants. Hot dogs, sausages, processed meats, and even hamburger were shipped to other sites for further elaboration and additional value. That also kept work standard and wages low compared to the plants that were closing in the Midwest.

In 1967, IBP perfected an innovation that dramatically changed the industry—boxed beef. Instead of shipping beef to customers in whole carcass form, as the industry had done for years, IBP mastered a process in which the packer breaks down the carcass into smaller portions. These cuts are then vacuum-packed and shipped out in boxes. While boxed beef was initially sold to the hotel, restaurant, and institutional trade, they soon shipped it to retail groceries as well.

Through this “butcher friendly” concept, it became possible to eliminate more than 250 pounds of fat, bones, and trimmings, which were of very little value to the retail and food service customer. Boxed meat improved quality, provided easier merchandising at the retail level, improved shelf life, and saved energy, transportation, and labor costs. This major innovation in beef processing came with the 1967 opening of a boxed beef operation at IBP’s new Dakota City plant complex. It was the first large-scale beef processing plant in the nation. Dakota City also became the new location of the company’s headquarters.

The advent of boxed beef changed the structure and geography of the entire meat industry. Now, instead of shipping carcasses, the packing plants cut the beef down into wholesale pieces and vacuum packed them into boxes. This greatly reduced the amount of work for wholesale butchers and also decreased the amount of space needed for shipping. In the 1970s, fuel and transportation costs were at an all-time high in constant dollar terms. Boxed beef allowed the packer to add more value to the product at the plant, to reduce transaction costs in shipping, and it reduced labor costs for urban retail grocery chains. It also reduced the power of grocery store cutters, as the retooling of the plants in rural areas reduced the power of the workers on the floor. Stores were able to bypass the skilled labor union members for meatpacking and distribution by hiring low-skilled workers to do repetitive tasks that were relatively quickly learned; turnover was high due to poor working conditions but labor was plentiful as long as unemployment was relatively high or there was a plentiful supply of immigrant workers. That strategy that linked new technology to new workers lowered costs and pushed the balance of power in the industry in favor of the packers and the grocery chain and against cattle growers and packing plant workers.

## Procurement

**Husbandry.** Calves are generally conceived either through artificial insemination (increasingly the case in developed countries) or by bulls, in the case of larger herds, or borrowed for the occasion for smaller herds. Calves are raised on grassland or rangeland with their mothers until weaned, then usually sold to a stocker feeder who will bring them up to around nine hundred to a thousand pounds on rangeland, pasture, or crop residues. Prior to slaughter, cattle often enter a feedlot, where they are fed high-protein feed and fattened.

Artificial insemination (AI) is little used in cow/calf operations in the western half of the United States. Most herds depend on bulls. One bull for each twenty to thirty cows is usually recommended. The biggest deterrent to using AI is the extra labor needed to detect cows in heat on open range and then to confine them for individual insemination. The problem was partially overcome with the approval for use of hormonal materials that can be injected to synchronize estrus. More than half of an entire cowherd may be bred successfully during a single day by a skilled inseminator using AI and estrus stimulation.

Birthing difficulties are one of the most costly problems in calf production. As a result, American ranchers typically breed their heifers to Longhorns in order to get low birthweight calves—but this results in substandard beef.

Cow/calf producers normally rely on grazing. Nutrients obtained through grazing are usually less costly than those provided through harvested forages, grains, or other processed feeds. In addition, the dispersion of cattle grazing helps to minimize other problems, such as disease epidemics. Lowering the risk of disease decreases production costs and also reduces the need for labor. The western United States dry native range, on which agricultural operations are minimal, provides an overwhelming share of the grazing. The area necessary to support a cow depends on the amount of rainfall—the less the rainfall, the more acres required to support each head of livestock.

The stocker feeder generally uses pasture and rangeland as well as crop residues for feeding. The cattle still harvest most of their own food. Increasingly, stocker feeders are using rotational grazing (particularly in Australia and New Zealand), which helps them raise more cattle better on less land and keep the land in better condition.

There is a disjunction between the cow/calf operator or stock feeders and the feedlots/packers, which results in a very fragmented commodity chain with a great deal of distrust between the stages. The first two stages manage the resource. The last two stages manage the market.

While much of the world prefers grass-finished beef, the United States and Canada have focused on corn-fattened beef. Grain farmers who raised cattle on their uncultivable land fed their cattle using their own

The use of cattle as draught animals has declined considerably since the introduction of tractors, but in rural Romania it is still a common sight. This team of bullocks is at work in fall plowing in the village of Hobbitza. © ADAM WOOLFITT/CORBIS.

grains. While farm feedlots were dominant through the 1960s, changes in the tax laws in the 1970s made investment in “agricultural” enterprises extremely profitable. Capital moved into stand-alone feedlots, first from rural professionals, then from their urban kin and friends, and finally from corporations. The relocation of the feedlots, in turn, impacted corn production. As the large feed lots moved to more arid areas, where waste management was easier and population less dense, demand for corn increased. Beef fattening became more concentrated and shifted west.

Biological and mechanical technology worked together to standardize beef production in order to maximize packer convenience. Packing plants demanded uniform-sized carcasses to maintain the speed of the disassembly line. Adjusting the height of the chain that carried the carcass around the plant was time consuming. At the same time, hormones were being introduced to increase rate of growth and improve feed conversion. While there is some evidence that the injection or implanting of hormones or steroids may toughen the meat and affect flavor, it does add extra weight. Animals were slaughtered at the same age and much higher weights, in essence increasing the supply of beef.

**Slaughter and processing.** Traditionally, small farmers around the world raised cattle from calf to slaughter (although in many parts of Africa, as in North and South America, beef cattle were not herded by their owners). Once the productivity of the animal had declined or feed supply became scarce, it was either slaughtered for home consumption or taken to an *abattoir* or butcher to be slaughtered, disassembled, and sold.

The division of labor between cow/calf operations, stock feeder operations, and fattening operations was established in the early part of the twentieth century. By

that time, the industry had taken on its current form—very centralized packing operations with close ties to wholesale and retail distributors linked to feedlots, feeders, and cow/calf operations. Industrial concentration increases as the animals grow older. There are a great many cow-calf operations, slightly fewer stock feeder operations for the weaned calves, many fewer feedlots, many fewer packers, and a decreasing number of wholesalers, now mostly linked to retail chains.

Before World War II, retail stores bought quarters and sides of beef and cut them into “primal cuts” and retail cuts. After the war, consolidation of the retail grocery industry proceeded very rapidly, as local butcher shops and single-store operations were closed. One of the major ways supermarkets had of increasing profits was decreasing labor costs. Self-service, which required less labor to gather customer orders, now included meats, replacing the butcher who had previously cut and wrapped meat to each customer’s specific request. Supermarket corporations particularly welcomed the central processing of meat, which allowed them to reduce the number of meat cutters who were their highest paid workers. Box beef was an innovation that met the needs of supermarket chains, as net profits declined between 1967 and 1974 to 0.8 percent, 60 percent of their previous level, and real wages grew over 7.5 percent per year, or 50 percent faster than before (Walsh, 1991, p. 452). Thus the retail part of the beef industry was ready for packaging innovation. That innovation, boxed beef, impacted the geography as well as the structure of the meat-packing industry by moving beef processing from urban centers, where, as a mature industry, it was highly unionized, to rural areas near feedlots and sources of grain, particularly corn. As these areas were sparsely populated, it was necessary to recruit a labor force, and new migrants from Asia (particularly Southeast Asia), Latin America (particularly Mexico), and Africa (particularly Somalia) moved to the rural packing plants to take the jobs.

**Storage.** Consumers prefer fresh beef to frozen beef. Yet beef has a relatively high spoilage rate. Spoilage is averted by keeping bacterial counts low, which is accomplished through plant cleanliness, careful slaughter procedures that prevent *E. coli* from the intestines from coming into contact with the carcass as it goes to be disassembled, and keeping temperatures low so that the bacteria multiply at low rates. Reducing the oxidation of the meat after aging, that is, minimizing contact with oxygen in the atmosphere, is also a factor. Refrigerated cars and trailer trucks help reduce spoilage, as does consuming the meat shortly after it is produced and slaughtered. Irradiation of beef is now highly promoted by the industry to increase shelf life, but meat processors have been reluctant to introduce this procedure because of consumer concerns related to its impact on beef quality and safety.

Aging the carcass adds tenderness and flavor, but adds cost in terms of storage space and time in inventory. After slaughter and initial disassembly, beef is moved within the packing plant to a refrigerated room kept at a temperature between 34°F and 38°F. This cools the meat and firms it prior to shipment. The meat is generally kept refrigerated for 24 to 36 hours. Fresh beef can be held for several weeks at this temperature, and prime beef is sometimes held for five or six weeks long to “age” it. Fresh chilled beef must be shipped in specially refrigerated cars and ships in order to arrive in good condition.

**Distribution.** There is increasing vertical integration between the international companies who own the packing plants and retail grocery chains. While beef has traditionally gone through a series of brokers and wholesalers, the links in the commodity chain have been reduced for a number of major grocery chains such as Walmart. This vertical integration has been coupled with an increase in branded beef for supermarket sales, which was unheard of in the early 1990s. Restaurant chains are also forming tighter linkages with packers and even feedlots, stock feeders and cow/calf operators, as consumer demand for particular qualities in appearance and taste, as well as how an animal is raised, become more important.

**Changes in the means of procurement over time.** Carcasses are graded for quality, which is assumed to be related to taste and tenderness. The price paid by the packing house depends in part on the grade the carcass receives and that day’s demand for the different grades. Different nations have their own grading standards. Grading standards change over time, but relatively slowly. In part, that is because each stage of the system defines quality differently.

Despite increasing concentration in feeding and packing, the beef cattle industry is disjointed and dispersed because of its dispersed resource base. There are over one million cow-calf herds in the United States, down 2 percent between 1996 and 1997. The average cowherd consists of fifty cows. Thirty percent of calves come from 700,000 herds, averaging fifteen heads of cattle. Sixty percent of cattle end up in 215 different feedlots. This dispersed base funnels through the auction markets, which still play a dominant role in the cattle industry, into gross economies of scale in the form of feedlots and packing. The cattle industry is a scavenger industry, in that its nutrient fuel base varies widely and ranges extensively, and includes grass, crop residue, and wheat that otherwise might not be used for commercial purposes. And there are difficulties in linking the different parts of the value chain when one part is based on managing the available resources (cow-calf operations and feeder cattle operations) and another is based on responding to market timing (feed lots and packers).

American beef exports have increased from less than one percent of production in the 1970s to around 9 per-

cent by 2000. In general, imported beef competes with U.S. dairy cull cows in the production of hamburger. Imports have averaged 9 to 11 percent of beef consumed in the United States since the mid-1980s, with the level in any year depending on the phase in the American cattle cycle. For example, at the peak of the cattle cycle in 1996, less than 8 percent of the beef consumed in the United States was imported, compared to over 11 percent in 2000.

## Preparation and Consumption

**Preparation.** Beef can be preserved and prepared in many ways. Early preservation involved salt: meat was salted and dried or placed in a brine of salt water. Beef is still salted and dried in many parts of the world, providing portability and flexibility in storage and consumption. The dried beef can be eaten dry or reconstituted in sauces. Prior to the advent of canning, corned beef was shipped across continents to feed armies stationed abroad. But with the advent of the canning process, corned beef could be more easily shipped and stored for a wide range of purposes. Relatively large pieces of fresh beef are preferred in Europe, Australia and New Zealand, and the Americas. In Asia and Africa, beef is eaten more often, but in smaller quantities than in the West. In some cultures, beef is a condiment, served in highly flavored sauces with grains and legumes.

Different cultures have different ways of cutting beef and defining beef quality. In France, where hormone injections and implants are illegal, male cattle are not castrated until they gain full size. The preferred animal is older, slow growing, grass-fed, and the meat is darker in color. In North America, animals are killed younger, grow faster through the use of hormones and nutrient-rich feeding, and the meat is lighter in color in the meat case. These cuts of beef are often grilled (requiring marbling) or fried. Groups of European origin also bake and boil various cuts of beef. Braising, simmering, roasting, broiling, soups, and stews are other ways that specific cuts of beef are made palatable. Beef is also eaten raw, chopped fine for beefsteak tartare and beefsteak *à l'américaine*. Beef is often cooked with alcoholic beverages, such as beer and wine, to tenderize it and add flavor.

The introduction of European genetics led to four modern Japanese breeds that are known as *wagyu*. They are valued because of their wonderful taste and extreme tenderness. The meat is thinly sliced and placed in boiling water along with a variety of vegetables, resembling a traditional method for cooking fish and vegetables for *shabu-shabu* and *sukiyaki*. High marbling is required to maintain its tenderness during the boiling process. Beef is served in many cultures with a wide variety of root crops and vegetables

**Types of beef.** Almost all parts of the animal are used as food. Western cookbooks include recipes for brains, blood, heart, kidneys, liver, lights (lungs), sweetbreads (thymus gland), tongue, and tripe (the lining of the third

stomach), which are particularly used in regional cooking. In addition, beef heads were made into head cheese and the feet used in soups in many cultures. Use of these less desirable cuts came from peasant households, who invented delicious but labor-intensive ways to utilize the parts rejected by the upper classes.

## Consumption

**Traditions.** Because of the multiple functions of cattle and their breeding potential to increase wealth, many societies in Asia and the Pacific developed strong taboos against killing cows or healthy bulls. Only worn-out work animals, barren cows, and unwanted calves were sold for slaughter or consumed within the household. Thus many of the ways of cooking beef involved long, slow cooking.

Many cultures around the world consume beef. Its consumption is permitted by all major religions of the world except Hinduism, although Buddhism discourages the eating of the meat of four-legged animals, including beef. For many years, in India, which had a very high cattle population (and even higher if one counts water buffalo), it was illegal to kill cattle, and slaughter of buffalo was highly restricted. Japan only revoked the ban against eating meat in 1882, soon after the Meiji Restoration. Shinto also had strong norms against showing of blood. Thus butchers cut the beef very thinly. Christianity views eating meat, particularly beef, as highly desirable and a sign of self-indulgence. Thus the giving up of meat during holy seasons, such as Lent, and on Fridays becomes a symbol of sacrifice, replicating that of Christ for the world.

Generally, beef is a meat for the wealthy. Nations that are large producers of beef also tend to eat very large pieces of beef relatively often. As nations' fortunes rise and fall, so does their per capita beef consumption. For example, the economic slowdown of the 1980s decreased Peruvian beef consumption, and the economic problems at the end of the twentieth and the beginning of the twenty-first century have reduced the traditionally high consumption of beef in Argentina.

## Nourishment

While beef provides important nutrients, particularly iron and key amino acids, it is also a source of fat and cholesterol, although the concentration varies, depending on the cut of beef and how the animal was raised.

## Symbolism

**Ritualism and traditions.** Cattle worship was widespread in the cattle cults of the Mediterranean basin. The crescent of the cow horns was seen as imbued with the life-giving power of the crescent moon. Cows, in particular, figure as symbols of fertility in parts of Asia and Africa.

Cattle are viewed as sacred in the Hindu tradition. Beef is not consumed, nor are cattle unduly constrained.

But the by-products of cattle form an important part of peasant survival strategies in many rural areas. Their manure provides building materials, fuel, and fertilizer, and the animals themselves provide traction to raise the grains and pulses that are the staples of the South Asian diet. The prohibition against killing cattle ensures that even in times of hunger, the means to produce the following year will be in place.

Cattle have a paramount and pervasive symbolic value in many parts of East Africa, where they represent social status as well as wealth. As a result, the supply of cattle exceeds the demand for their meat, milk, hides, traction, or other uses to which they are put. In particular, the use of cattle for meat and hides or their sale for cash reduces the status of the head of household. More recently, the size of cattle corrals has proven to be an excellent proxy for the household wealth and status in communities in much of Africa. Cattle have critical symbolic importance in ritual, dance, marriage, and other aspects of social relations. For example, in many cultures the marriage contract calls for the payment of bride price to compensate for the loss of the services of the young woman to her parents. This is often negotiated in terms of number of cattle, delivered in installments: at marriage, the birth of the first child, and at the birth of the second child, at which time the marriage process is seen to be complete.

### Global and Contemporary Issues

**Commercialization.** Over 48 million metric tons of beef were consumed globally in 2000, an increase of slightly over a million-and-a-half tons since 1995. Beef production worldwide exceeded consumption in 2000 by over a million metric tons, a pattern of overproduction that has marked the end of the twentieth and the beginning of the twenty-first century.

Generally, beef consumption increases with a rise in middle class incomes. The Argentina consumes the most beef per capita, followed by the United States, Australia, and Canada. The United States consumes the largest total amount of beef annually (around 12 million metric tons a year), followed by the European Union, the People's Republic of China, and Brazil. Canada, Mexico, Colombia, Argentina, and the Russian Federation are also major beef consumers.

Between 1995 and 2000, beef consumption increased 49 percent in India and 32 percent in the People's Republic of China. In contrast, during the same period it declined 28 percent in the Russian Federation and 19 percent in Poland. It did not decline further in the Russian Federation because of beef that came in the form of food aid. Unlike Europe, the United States does not have a direct subsidy program for beef, although it often steps in as a buyer to help keep market prices up. That beef is exported as food aid, and used domestically for school lunches and at military bases.

The United States trades an increasing amount of dressed beef internationally. The U.S. had a cattle inventory of 99.5 million head in January of 1998 (USDA/NASS, 1998), compared to a world cattle inventory of 1,323.3 billion head (FAO, 1998). While the numbers of American cattle rise and fall in approximately 18-year cycles, with numbers increasing with each cycle, world cattle numbers have shown a general increase since 1961. The current cycle peaked in 1996. With the large herd destruction in Europe in 2001 due to animal diseases, the herd shrink will increase.

Australia exports the most beef, followed closely by the United States, which is the second largest international beef exporter (primarily high quality beef) and the largest beef importer (primarily low quality beef to be made into hamburger). The United States consistently imports more beef than it exports. Japan is the second largest importer of beef. Between 1995 and 2000, beef exports increased the most in Canada and Brazil, followed by India and Uruguay. China and Australia decreased beef exports during this period, perhaps related to the increased consumption in both those countries. Mexico's beef imports increased over five times during the six-year period, as its economy gained a solid footing. However, imports dropped in many countries during that time period. In South Africa, decreasing imports was coupled by increased production. But in both Poland and the Russian Federation, both imports and production dropped substantially.

**Consumption patterns.** Beef is increasingly consumed in institutions and restaurants rather than at home, following the trend of most foods. Many cuts of beef require long cooking times, whereas restaurants tend to offer quick cooking cuts such as hamburger and steaks. Condiments and sauces give the meat flavors once provided by long cooking with herbs and spices. A variety of tenderizers are used to substitute for lack of aging, unreliable genetic origins, and short cooking times.

Beef is often eaten in the form of hamburgers, as the whole place and pace of eating changes in America and other places of the world. Where the ritual of family dining continues, beef often has an honored place, but the shift of women's work from the home to the factory and office has reduced that practice. Beef for home consumption is increasingly ground beef, with a growing market in packaged foods that can augment the ground beef and give it a homemade gourmet patina.

Beef that has been prepared to be carried out or home delivered, particularly as pepperoni or hamburger pizza, is increasingly popular, not only among the young but among working couples who would like to eat at home but have no time to cook. Increasingly, work place cafeterias are providing after work take-home meals for company or agency employees.

Institutions serve beef often, including in school lunchrooms (increasingly through franchisers, including

fast food purveyors), hospitals, nursing homes, and prisons. There are fewer dietary restrictions on beef than pork among ethnic groups, increasing its utility in many institutional settings.

While beef has long been part of ready-to-eat soups and entrées, there are increasing attempts to make beef easier to cook and tastier—perhaps in response to the use of less tasty, less tender, quick-maturing breeds and hormone use to speed growth in the United States, where, unlike in Europe and Japan, early maturity is preferred over taste and tenderness. (However, the USDA firmly states that hormone-raised beef is extremely tasty and tender.) Beef is thus available at retail in stir-fry or fajita slices that have been marinated in a wide array of herbs, spices, and tenderizers. This cuts cooking time and gives a wider menu variety to the working chef and eater.

**Types of consumption.** Cattle and calf meat is consumed directly as meals and snacks, and its by-products are used in a wide number of foods, from gelatin to ice cream. In the United States, direct per capita beef consumption declined from 81.7 pounds to 63.8 pounds in 1997. More recent data suggests that U.S. beef consumption is increasing from the low in the years 1992–1996 of 63.5 pounds, in part in response to economic expansion.

**Issues surrounding consumption.** Cattle have proven to be a source of conflict at all stages of their production and consumption. On rangelands and pasture, there is great concern about: 1) overgrazing and its negative impact on biodiversity, soil quality, and hydrology; and 2) contamination of streams when cattle are allowed to freely wander in them. While research and practical experience have shown that cattle can enhance grassland and rangeland, that is often not the case, and cattlemen and women are generally extremely suspicious of environmental constraints, since they are seen as potentially infringing on the rights of the cattle operators to use their land and the land they rent (whether from the government or from their neighbors) as they see fit.

Cattle raising has been the cause of a great deal of deforestation in tropical areas of the world. Settlers clear land, selling valuable timber to transnational companies. The newly cleared soils are planted with fast-growing pasture that often is relatively impervious to water, increasing runoff. Cattle are grazed for the low end of the beef market, ending up in fast food outlets in developed countries.

In Europe and increasingly in America, there is concern about how cattle are raised and treated. There is growing concern about the stress animals undergo in large feedlots, which some believe affects the taste of the meat. Modern packing plants have tried to decrease stress at the time of slaughter to reduce the adrenalin in the muscle tissues, which toughens the meat and gives it an off-putting flavor. Concern for animal welfare is coupled with health and environmental concerns surrounding large feedlots and packing plants.

Europe does not allow injection or implantation of hormones, which is a standard practice of most producers in the United States. In fact, stocker feeders inject their cattle with hormones on penalty of not being able to sell them to a feedlot. If the cattle are not injected in the neck, meat quality will be negatively impacted around the site of injection, which is often easiest to administer into the prime cuts. Hormones increase the rate of growth and nutrient utilization, but increasing evidence suggests that they negatively impact meat taste and tenderness. They are also viewed as a health hazard in Europe, as well as having a negative impact on animal health, as the use of these steroids puts additional stress on the animal. As a result, Europe banned American beef produced with artificial hormones in 1989, which has resulted in a continuing trade battle.

Mad cow disease (bovine spongiform encephalopathies, or BSE) has been linked to the fatal Creutzfeldt-Jakob Disease (CJD) through human consumption of meat from cattle with the prion disease. It is thought to be transmitted from one animal to another through the consumption of bone meal from sick but undiagnosed cattle or sheep and from animals to humans by eating meat that contains prions transferred by the nervous system. Thus the brains and the meat that is in contact with the spinal column are particularly suspect. In parts of Europe, the sale of meat on the bone has been forbidden. As a result, beef consumption has dropped precipitously and exports have been banned altogether.

Foot and mouth disease outbreaks can cripple production and exports, as occurred in Britain, Argentina, and Europe in 2001. In contrast to BSE, foot and mouth disease is not transferable to humans, but it is easily passed among hooved species and greatly reduces the productivity in infected cattle herds. Increased globalization of the food system may be related to both outbreaks.

**CENTRAL AMERICA.** Central America is an isthmus, or land bridge, that unites the two continents of North and South America. It consists of seven countries: Belize, Guatemala, Honduras, El Salvador, Nicaragua, Costa Rica, and Panama. Except for Belize, all of these countries were first settled by the Spanish in the early 1500s and remained part of the Spanish colonial empire until they revolted for independence in 1821. The culinary history of the three-hundred-year colonial period has not been studied as thoroughly as it has in Mexico or in South America, in part because many documents relating to the area are housed in Spain rather than in local archives. Furthermore, while Central America attempted to unite politically following independence, that effort eventually failed. This political fragmentation has left a distinctive imprint on the culinary profile of the region. In spite of this, however, there are certain unifying features.

### Common Features

Geographically, the countries have a great abundance of volcanoes. This has had an important influence on the cuisine because the volcanoes have fertilized the soil with mineral nutrients that have made this one of the richest areas of biodiversity in the world. The gold the Spanish conquistadors had hoped to find was made up for by an exquisite natural beauty and an abundance of unusual food plants, both cultivated and wild. Due to this rich soil, the region has become a center of coffee production.

Another unifying feature is the composition of the people themselves. The population of Central America consists mainly of four groups: mestizos, a mixture of Spanish and native peoples and the largest group; small pockets of indigenous populations; Africans; and people

of unmixed European descent sometimes referred to as Creoles. Throughout much of the region, African populations are concentrated along the Atlantic coastline, while mestizos populate the Pacific side. The central area of the isthmus is home to a lush rainforest sparsely populated by small groups of indigenous tribes.

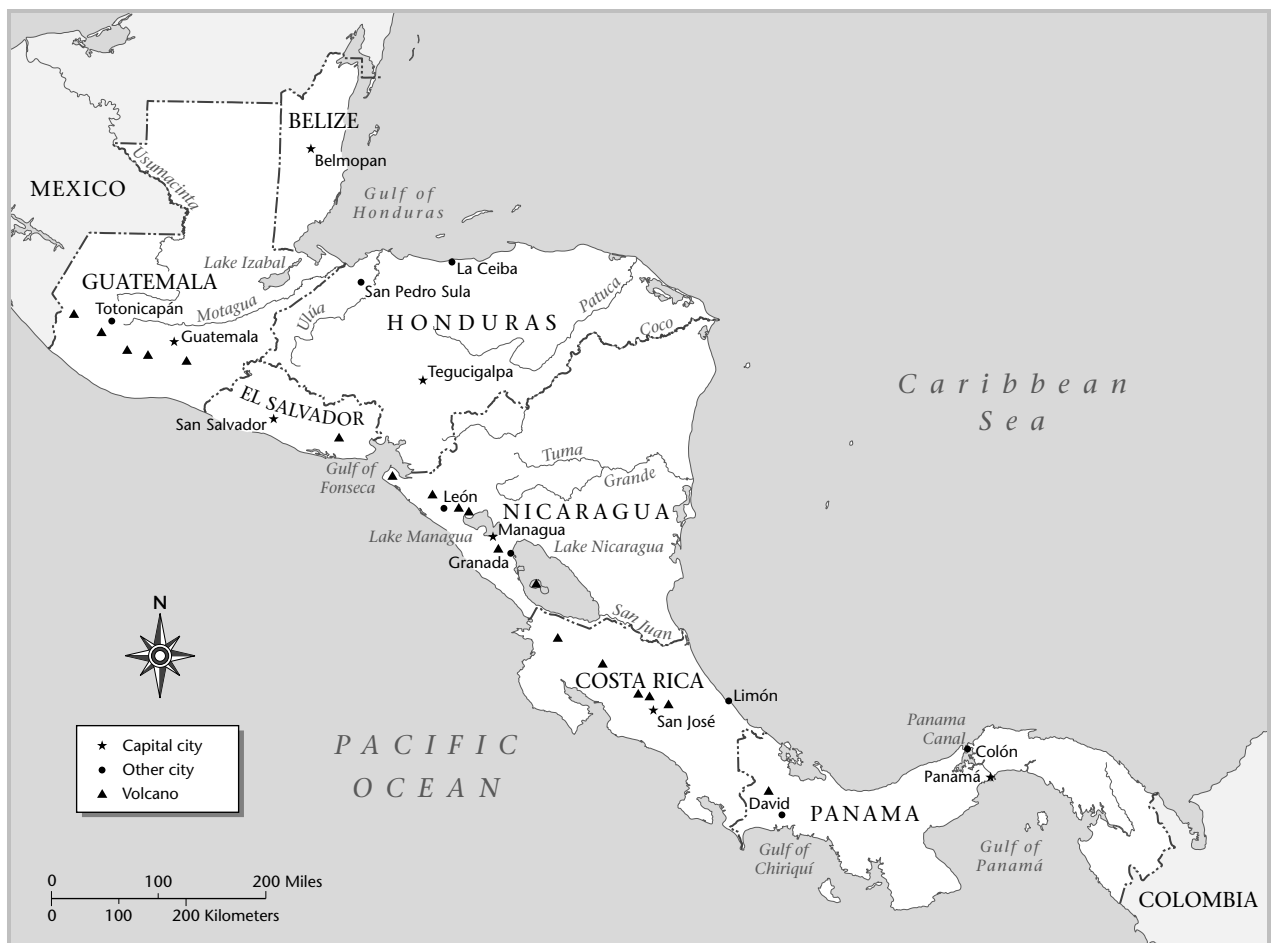

The African population descends mainly from runaway slaves who escaped from Jamaica and neighboring Caribbean islands. They have preserved a dialect of English infused with African vocabulary. This group has made Central America more diverse in language as well as in cookery, since its cooks have blended together African and indigenous food preferences. One of the typical ingredients is coconut: shredded coconut, coconut milk, or coconut oil. Except for smaller indigenous tribes like the Miskitos of central Nicaragua, coconut is not widely favored by the other ethnic groups.

In terms of cookery, the mestizos have mixed traditional indigenous dishes, mainly preparations of Mayan origin, with old Spanish prototypes, but in some instances the two cooking traditions have been kept separate. The smaller indigenous tribes still remaining in Central America rely mainly on hunting and gathering and have not influenced the cookery as much as larger groups, such as the Mayans.

One of the characteristics of all Central American cooking is the use of fresh ingredients, from fresh meats and vegetables, to tortillas and breads made to order, even dairy products prepared the same day. The markets abound with the sweet aromas of tropical fruits and vegetables displayed in an endless sea of colors. The market is especially important as a stage for lively social exchange, and since the cooking traditions of Central America are mostly oral rather than based on cookbooks, recipe discussions in the marketplace serve as a major conduit for ideas and the comparison of family cooking preferences.

Oral tradition is a key to understanding Central American cookery: most recipes are handed down from generation to generation by word of mouth. In middle- or upper-class families, it is customary to have an in-house cook, but someone in the family is assigned the task of teaching the cook the way a dish should be prepared. Special instruction and attention are required for dishes that have been handed down within the family and are usually prepared only on special occasions. Although the choice of recipe ingredients may vary within each country and family, there are still quite a few standard national dishes that have been maintained over a long period of time and have not undergone much variation. Outside the region, little is known about the cookery of Central America because many of the key recipes are not written down, except perhaps in a small number of local cookbooks of very recent date.

Beef is an important meat in Central American cooking because of the large number of cattle ranches, which

provide beef both for local consumption and for export. The flavor of Central American beef is very different from that of the beef of North and South America, in part because the animals are grass-fed and thus leaner, but also because the Criollo breed of cattle is itself quite distinctive. The flavor and texture of its meat more closely resemble veal than beef.

It was customary for a middle- or upper-class family to have beef at least once a day, especially in Nicaragua. New dietary trends have changed a few old traditions so that now people mindful of their health are eating less red meat, yet beef is still a luxury for the poor. For those who prefer to eat less red meat, beans are a common substitute. Beans are said to be one of the staple foods of the poor, but they are very popular among all social classes. Once boiled, the beans may be sautéed with onions, sweet peppers, garlic, salt and pepper, and some of the cooking broth may be added. The result is a simple yet tasty dish. A common preparation consisting of beans, boiled plantains, and cheese forms a one-pot vegetarian meal that is nutritionally balanced as well as pleasing to the palate. Many of the most popular dishes of the region are studies in simplicity, since light food is a welcome reprieve in the hot climate.

Contrary to popular belief, Central American cookery is not spicy, except in Guatemala where the chili pepper plays an important role as a spice. Elsewhere, chili pepper is an optional ingredient, except in some dishes where it is considered critical, but one is always given the option to choose between something spicy or not. At most meals, a bowl of hot sauce or a salsa consisting of a mixture of tomatoes, garlic, onions, and sweet and hot peppers marinated in lime juice provides added spice and flavor for many dishes. There are many other variations of salsas containing chili peppers, such as *encurtido*, a mixture of chopped vegetables pickled in vinegar with hot peppers. In this case, the spicy vinegar brings out a variety of subtle flavors in the dishes eaten with it. Most meat preparations are marinated in a mixture of black pepper and sour orange or lime juice, giving them a cleaner and more complex taste. The sour juice is important in tenderizing, flavoring, and sterilizing the meat.

The annatto is another important ingredient in the cookery of this region. Annatto is the seed of an indigenous tree (*Bixa orellana*), better known in other parts of the world for coloring cheese; it is this ingredient that dyes the cheese orange or yellow. The cultural importance of annatto dates back to pre-Columbian times when

it was used for special rituals. The Mayas and other indigenous populations employed it as body paint during religious ceremonies, and also for coloring pottery, for monetary purposes, and for flavoring certain foods. Known as *achiote* in Central America, the seeds are ground and mixed together into a paste of black pepper, salt, and vinegar that is then diluted in either sour orange juice or lime juice and used to marinate or preserve meat. Historically, *achiote* was used to preserve meats from spoiling in the tropical heat. Today, *achiote* creates a delicious marinade for grilled meats. It seems to have little taste as a raw paste, but when heated, it undergoes a chemical change that releases a complex array of flavors. While *achiote* lengthens cooking times, it also prevents meats from scorching or drying out while they are being grilled.

Rice is a key element in every Central American meal and is one of the important culinary contributions from Spanish cookery. After careful rinsing, rice is usually sautéed in oil with onions until toasted; water is then added, with a little salt to taste. Toasting causes the grains to remain fluffy, and the onions impart a subtle aroma and flavor that complements many entrees. In fact, Central Americans commonly judge the abilities of cooks based on the fluffiness of their rice, for it is said that if one masters the art of cooking rice, one has mastered the art of cooking.

There are numerous rice dishes in the region that are similar to Spanish paellas, such as *arroz a la Valenciana* in Nicaragua. This consists of a mixture of chicken, pork, shrimp, and sausage cooked together with rice and vegetables. *Arroz con pollo* is another popular dish served throughout the region from Guatemala to Panama. Although the recipe varies, the essential mixture and texture is common, consisting of chicken and vegetables cooked together in a stew; rice is then added. This recipe has much more broth than the Nicaraguan *arroz a la Valenciana*, and *achiote* is added as the substitute for saffron.

Throughout Central America, maize is doubtless the single most important culinary element in all of the regional cookeries. Maize was so important to the indigenous peoples before the arrival of Columbus that in Mayan mythology man and woman were created from two maize kernels. It was seen as a life-giving element and it has greatly influenced the cookery of Central America. The tortilla, made from maize flour and water, is usually present in at least one daily meal. It is traditionally eaten while still warm and accompanied by several types of salty cheese. There are people who specialize in making tortillas and can shape the dough between their hands in a matter of seconds, until it reaches a circumference of approximately 10 inches (25 centimeters). The tortillas are then placed on a hot griddle, lightly scorched, and rushed to the table while still steaming.

Maize is also the ingredient for many refreshing drinks and is fermented to create an alcoholic drink

known as *chicha*, which can also be consumed before full fermentation takes place. This old indigenous beverage has changed very little over time, except that now sugar is used as a sweetener rather than honey. *Chicha* is a generic term used by the early conquistadors to describe any alcoholic beverage in the New World, but there are actually many variations of *chicha* throughout Latin America.

*Atole* is another drink made from maize that is mainly a feature of Guatemalan cuisine, but is present throughout Central America under many local variations. It is a filling, high-energy drink that can be either sweet or salty. *Atole*, typically served hot or warm, has a thick consistency and can be made from a wide variety of ingredients, the most common being milk, sugar, ground maize kernels, cinnamon, and cloves. In Nicaragua, *atole* vendors always seem to show up after a heavy afternoon rainstorm, making sure everyone warms up by drinking plenty of the beverage. It is especially popular in the cool mountainous areas of the region.

Tamales made from maize are popular throughout the isthmus and are prepared in a variety of ways, depending on the local cultures. Each country has a special variation of tamales, but aside from the different ingredients, they are always wrapped in either cornhusks or plantain leaves and steamed or boiled. Tamales can be eaten on any occasion, but in some countries, such as El Salvador, Costa Rica, and Panama, they are generally prepared for holidays. Traditionally, they are consumed during the Christmas season or at Easter. They can also range in size from dainty handheld appetizers to large main-course dishes. The most common forms consist of ground dried maize or the raw mashed kernels shaped into a thick, rectangular dough that is filled with different vegetables or meats, or simply sweetened with sugar. They are then wrapped in leaves and boiled or steamed.

Just as there are variations in ingredients, there are also variations in nomenclature. For example, in El Salvador, *tamales relenos* are similar to the Honduran and Nicaraguan *nacatamales*. In both Honduras and Nicaragua, there are tamales (boiled in corn husks) and *nacatamales* (boiled in plantain leaves), which vary from one another in their fillings. *Nacatamales* are difficult to prepare not only because of the complexity of the ingredients, but also because of the length of time they take to cook. In Nicaragua, there are people who specialize in making them since they are always in demand for parties or for traditional Sunday brunch.

Another way of using ground maize is as a thickener for stews or for giving a distinctive flavoring to certain dishes. Ground maize can also be toasted and used to flour meats or fish for deep frying. Water and sugar can be added to toasted maize to make *pinolillo*, a chocolate-like drink that is filling yet refreshing. In Honduras, *pinolillo* is also prepared with a touch of ground chocolate, thus giving it a more complex taste.

Central America is a paradise for natural fruit drinks, since it has a seemingly endless variety of fruits that can be mixed together to produce deliciously healthy and refreshing beverages. One can find a natural fruit juice stand on almost every street corner on hot, sunny days. Many Central Americans take a break before lunch and sit for a few minutes under the shade of a tree to cool off and relax with a tall glass of *refresco*, literally “refreshing,” with plenty of ice. The best drinks are made with ripe fruits, so that there is no need for sugar. These fruits can also be used for creating an enormous variety of sorbets, which are popular on hot, humid afternoons.

The plantain plays a much more important role in Central American cuisine than the potato. It is more or less a staple vegetable, and green or ripe plantains can be prepared in a number of ways. Although the plant is not native to the continent, it adapted very quickly to the climate and soil of this tropical region. Its leaves are used in wrapping foods, such as tamales and *nacatamales*, for grilling, and sometimes as eating utensils. The plantain leaves give the food a subtle yet rich flavor, and, when grilling fish, keep it from scorching and impart flavor to the meat. It is said that Nicaraguan *vigorón* is not authentic unless it is served on the plantain leaf, which functions as a plate. When the leaf is folded, some of the juice is released into the food, perhaps giving it its “authentic” flavor. The old colonial Nicaraguan city of Granada is well known for its *vigorón*, consisting of boiled yuca (cassava), a sour and spicy shredded cabbage salad, and crunchy pork rinds.

Another way of cooking the unripe plantain is to cut the fruit into paper-thin strips and fry them at a high temperature, thus making them crunchy yet not oily. This is a popular way of preparing plantains throughout Central America. They can also be grilled or boiled in water and accompanied by a salty cheese. The ripe plantains can also be boiled and baked with cinnamon, cloves, and cheese, resulting in a tasty dessert sweetened by the vegetable’s own natural sugars.

As a general rule, the indigenous peoples of Central America were originally vegetarian, eating meat only on special occasions and cooking with little or no oils or fats. The European method of frying and cooking with animal fat quickly changed the native cuisine, but it also made room for a new and inventive style of cooking. Besides the better-known meats such as pork, beef, chicken, and fish, other animal meats are also part of Central American cookery. The *gibnut* or paca, a large rodent that feeds mainly on wild nuts, is consumed in Belize. The *cusuco* (*Dasyus novemcinctus*), a species of armadillo, is eaten in several countries, but it is most popular in El Salvador, where it is mainly a feature of rural cookery. This meat is marinated in lime juice, then grilled, following the same method used for cooking iguana.

Iguana is eaten throughout the region, but, again, it is mainly consumed by country people. The iguana is

Central Americans have developed a special breed of cattle to withstand the hot, humid climate. This herd is grazing near Tegucigalpa, Honduras. PHOTOEDIT. REPRODUCED BY PERMISSION.

known to have a rich flavor because it feeds on fruits, and it is especially fond of papaya, which gives the meat a tender texture and sweet flavor. Many people consider the meat an aphrodisiac, and it can also be boiled in soup, an old home remedy for strengthening those who are sick. Furthermore, iguana was an important meat substitute during the colonial period, since the Catholic Church declared it a type of fish for consumption on meatless days. There are numerous methods of cooking iguana, but those who eat it generally prefer it grilled.

### Guatemala

Guatemala was once part of the heartland of Mayan civilization. The Mayan imprint on modern Guatemala’s culinary riches is present in its numerous traditional dishes, especially those with corn as the predominant ingredient. The country is well-known for the great variety of its *atoles*. One of these is *atole de arroz*, a sweet beverage with corn, rice, cinnamon, sugar, and chocolate as ingredients. In the cool and mountainous area of Totonicapán, there is an unusual (and probably very old) *atole* made with beans, salt, and ground chili pepper.

*Recados*, pastelike mixtures, are important in Guatemala and are used for marinating meats or as condiments

to bring out complex flavors in cooked dishes. The most common of these is *recado colorado*, which uses ground annatto as a base mixed with garlic, black pepper, cumin, and other ingredients depending on the local recipe. Of all Central American countries, Guatemala is the only one that uses the chili pepper almost as an essential part of its cuisine. Peppers are used as a condiment, or as a main dish such as *chiles rellenos* (stuffed peppers). The chilies are first fire-roasted, next filled with a traditional mixture of pork and beef, onions, tomatoes, cabbage, and herbs. They are then dipped in a batter, covered with breadcrumbs and fried, blending indigenous and European methods of food preparation.

## Belize

Located to the east of Guatemala, Belize is a country with a large native-born population of African descent. Formerly a British colony, it attracted immigrants from other parts of the Caribbean due to an extensive lumbering industry. It is also the only Central American country where English is the official language. In the western part of the country, the food is similar to that of Guatemala because of the border they share. This cuisine is a blend of Spanish and Mayan influences, yet the coconut is an important ingredient because of the predominating African influence.

One of the local delicacies is conch soup in which the meat from the giant conch, a mollusk, is cooked with okra, green plantains, onions, lime juice, chili peppers, and coconut until it acquires a thick consistency. Belizeans are as proud of their conch soup as they are of their popular stewed beans with pork or beef. Stew beans are prepared by boiling meat with the beans, onions, coconut milk, herbs, and spices (depending on personal tastes); they are served with rice. *Garnaches* and *salbutes* are common dishes and can be served either as a main meal or as appetizers. These are thin, crispy deep-fried tortillas served with beans, cheese, and cabbage on top and may also be accompanied with chicken. In May, the cashew festival, which evolved out of the English May Day celebration, takes place. This festivity includes plenty of food and live music, as well as locally made cashew wine.

## Honduras

Honduras has a diverse cuisine that shares many similarities with that of Nicaragua, its neighbor to the south, including the influence of African-Caribbean culture. An outstanding Honduran dish is the popular *sopa de caracol*, or conch soup. In this recipe, fresh carrots, chayote, chickpeas, celery, onions, plantains, and baby corn are sautéed in butter and added to a clear broth flavored with *culantro*, a native herb similar in flavor to cilantro, but stronger-tasting. Coconut is then added to the broth along with some milk, the conch meat, achiote, and parsley as the garnish. The result is a flavorful soup with an African-Caribbean touch.

*Capirotadas*, commonly eaten during Lent, are small dumplings made from maize flour and water, filled with cheese, and then lightly fried until brown. The dumplings are subsequently added to a vegetable broth and enjoyed as a main meal. Another variation is to add syrup cooked with cinnamon and cloves, which is then served on the dumplings, creating a tasty yet simple dessert. *Pinole*, a slightly coarse, ground maize, is used as a thickener in dishes such as *gallina en pinol* and *iguana en pinol*. In both recipes—the first made with chicken or (preferably) hen and the second with iguana—toasted maize gives the meat a light nutty taste that complements the mixture of meat, herbs, broth, and vegetables.

## El Salvador

El Salvador is the smallest Central American country and the only one without an Atlantic coastline. The cuisine of El Salvador is popular throughout the isthmus because of its famous *pupusas*. Although there are similar variations of these tortillas in most Latin American countries, El Salvador has gained recognition for having what are generally considered the best recipes. *Pupusas* are basically tortilla dumplings filled with either cheese, small pieces of *chicharrón* (pork rinds), a mixture of both, or beans. The dumplings are then covered with *curtidos*, a combination of cabbage, shredded carrots, and chilies infused in vinegar.

## Nicaragua

Nicaragua is the largest country in Central America, and until the 1970s it was also the wealthiest. Its cuisine varies greatly from region to region, from old Spanish dishes such as *relleno*, *salpicón*, or *indio viejo*, to more indigenous preparations like *nacatamales*. *Relleno* literally means “stuffing” and in its original Old World form was probably used for stuffed fowl or empanadas. Like many Spanish dishes of medieval origin, it uses ingredients now associated with desserts: dried fruit, milk, nutmeg, sugar, and shredded bread as a thickener. Along with these ingredients, pork, olives, finely diced carrots, onions, mustard, capers, and vinegar or wine are blended into the mix. The result is a sweet and sour dish in which the diverse ingredients seem to come together harmoniously. Due to long, slow cooking and hours of constant stirring, this dish is so time-consuming to make that it is only eaten once a year, during the Christmas holidays. The large outlay of expensive ingredients, many of which must be imported, once set this dish apart as a class symbol of the old ruling families of the country during the colonial period, but today *relleno* has assumed the character of a national icon, especially to expatriate Nicaraguans.

Another dish of Spanish origin is *salpicón*, which is thought to have come to Nicaragua during the 1500s. The basic concept involves making a complete meal out of the basics for soup. It begins with beef boiled with an assortment of vegetables, most importantly ripe plantains. The meat is then taken out of its broth and finely chopped

The market at Chichicastango, Guatemala, is rich in local produce and in colorful native costumes. © TIBOR BOGNAR/CORBIS. CENTRAL EUROPE

with onions, sweet peppers, bitter orange juice, salt, and pepper. The boiled plantain is mashed, having already given the soup a subtle sweet flavor, and is then used as the dough for making empanadas. The empanadas are filled with the chopped beef and cooked rice that is to accompany the meal. A complete dinner is thus created by using as many ingredients as possible with little waste.

*Indio viejo* is similar to *salpicón* in that beef is boiled to create soup, but different in that the meat is then shredded and cooked again in its own broth with maize flour, spearmint, tomatoes, and, depending on family, recipes, *achiote*. The result is a complementary blend of Old World and indigenous flavors. *Nacatamales* also blend the Old World with the New, but the basic recipe has indigenous roots. Best described as fairly large dumplings made from maize flour, they are filled with capers, potatoes, onions, prunes, meat (pork, chicken, or turkey) marinated in *achiote*, tomatoes, and chilies. The dumplings are then wrapped in plantain leaves and boiled in water for several hours until all the ingredients are fully cooked. *Nacatamales* are usually enjoyed as Sunday brunch with strong black coffee.

### Costa Rica

Costa Rica is well-known worldwide for its natural beauty and perhaps also for its excellent coffee. Ecotourism has

helped the country's economy, but it has also greatly changed the local food culture. Aside from the more popular Americanized fast-food restaurants that are now common, the true cuisine of the Costa Rican people is the one prepared at home. Without a doubt, most Costa Ricans crave the popular *gallo pinto*, a mixture of white rice and beans cooked with a variety of fresh herbs and vegetables, creating a tasty meal of its own. This dish is eaten in most parts of the country at least once a day.

*Olla de carne* is another popular recipe that blends together a variety of vegetables and beef. This one-pot dish consists of squash, corn, yuca, ayote, and potatoes cooked together with beef in its broth, creating a very hearty stew. Round pieces of lightly mashed green plantains, known as *patacones*, are served during most meals and act as a substitute for the now ubiquitous french fries. During the Christmas holidays, Costa Ricans enjoy elaborate tamales, very similar to the Nicaraguan *nacatamales* in the variety of ingredients used as well as in the manner of preparation.

### Panama

Panama is a country defined largely by the Panama Canal, which has created a trading link between the Atlantic and the Pacific. During pre-Columbian times, the country was a center of older civilizations that specialized in gold

craftsmanship, using native animals as models for their works of art. Panama's culinary connection to this indigenous past was largely severed during the colonial period, when the region was part of what is now Colombia.

Created by the United States during the early 1900s, Panama and its canal attracted many immigrants seeking employment and new opportunities. This migration shaped modern Panamanian culture because of the large numbers of black laborers arriving from English-speaking islands in the Caribbean. The result was a blending of the local mestizo cuisine with that of the newly arrived immigrants. Panamanians keep their traditional cuisine alive at home, but they assimilated many African elements, especially the use of coconut as a main ingredient.

One example of the strong African influence is the popularity of *fufu*, particularly along the northern Atlantic coast of the country. Elsewhere in Latin America, *fufu* is a dumpling made of plantains or yams, but in Panama the term is applied to the entire stew. It is composed of a coconut milk base, boiled plantains, chilies, yuca, yams, and fried fish added at the end. *Saos* is yet another African-influenced dish adapted from the Jamaican kitchen. It consists of boiled calf's or pig's feet marinated in plenty of lime juice, onions, chilies, salt, and pepper.

In spite of the prevalence of these African influences, most Panamanians identify their national cookery with indigenous and Spanish preparations, especially *sancocho*, which is treated as a national culinary symbol. This dish consists of chicken cooked with vegetables, including yuca, corn, plantains, chayote, and potatoes, served with rice on the side. Panamanians seek relief from the mid-morning heat by enjoying the popular and refreshing beverage known as *chicheme*, which resembles *atole* because it is a maize-based beverage blended with sugar and cinnamon. Before lunch time, Panamanians like to enjoy a drink of *chicheme* with the tasty *carimoñolas*. These lightly fried dumplings consisting of boiled mashed yuca filled with ground beef, sweet peppers, tomatoes, and herbs can be eaten either as appetizers or as a main course.

**CENTRAL ASIA.** See **Asia, Central.**

**CENTRAL EUROPE.** For the purposes of this encyclopedia, Central Europe will be defined as the Czech Republic, Slovakia, Hungary, Romania, and Poland, although technically Austria and Germany played a critical role in the cultural development of the region. All of these countries were at one time completely or partly incorporated into the Prussian or Austro-Hungarian Empires and therefore shared in the transcultural culinary exchanges during the eighteenth and nineteenth centuries. Central Europe is a region represented by huge ethnic diversities, a complicated political history, and a wide range of microclimates, from Poland's cold Baltic winters in the north to the mild Black Sea climate of coastal Romania in the south.

From a geographic standpoint, most of the region is drained by the Danube River. The Carpathian Mountains form a natural barrier, cutting off Poland to the north and Romania to the east. The Transylvanian Alps in central Romania divide the region even further, and the Wallachian Plain stretches south across the Danube into Bulgaria. Hungary occupies a vast windy plain roughly corresponding to the ancient Roman province of Pannonia. The southernmost parts of this region were once under the political domination of the Byzantine Empire. This was followed by nearly five hundred years of Ottoman Turk influence.

The Czech Republic's kingdoms of Bohemia, Hungary, and Poland were all at one time major political and

cultural forces as well. The traditional foods of these three kingdoms were gradually incorporated into the court cuisine of the Austrian Empire, so by the nineteenth century they had become “Viennese.” The Wiener schnitzel (Viennese veal cutlet) would never have been possible without Hungarian beef; the famous *Kolatschen* (custard-filled pastries) of the Vienna coffeehouses would never have existed without the ancient *kolace* of Bohemia. As a political coequal to Austria, Hungary evolved a distinctive cuisine of its own inspired by nationalistic themes. Since Slovakia and Romanian Transylvania were once part of the Hungarian Kingdom, they experienced Hungarian influences most, but, by the same token, they gave back to Hungarian cookery added regional nuances and many specialized dishes.

While all of these countries were once unified in some manner under Austro-Hungarian rule, that unity disintegrated with the fall of the empire in 1918, after which they became independent states. At the close of World War II, and under the coercion of the occupying Soviet forces, all of the Central European nations were brought into the Soviet empire and remained within that cultural and political sphere until the fall of communism in 1989. Each of these nations became independent again with an earnest desire to rediscover the culinary past that was largely ignored for almost forty-five years. However,

the communist governments of all the Central European countries took considerable interest in ethnographic research and established many open-air museums and research institutes where rural life could be studied. While the motivation was political, the end result was a body of valuable archival materials much better organized than in some Western countries.

If there is a common theme to this discussion, it would be that linguistic and religious boundaries of Central Europe do not coincide with political boundaries. There are large minority populations in each country, and before the mass expulsion of Jews during World War II and of Germans at the end of the war, the diversity of minority populations was even greater than in the twenty-first century. This diversity created a patchwork quilt of foodways and local cookeries, all of which must be considered when viewing the region from a historical perspective. Yet regardless of the ethnic diversity, there are certain universal foods common to all the Central European cuisines. These include sour cream, dried mushrooms, poppy seeds, sauerkraut, horseradish, and smoked bacon. Bacon and bacon drippings provide one of the distinctive flavors of this region. On a par with this is the generous use of dill.

During the nineteenth century, movements for national independence turned toward rural peasant culture

to find a national cultural identity, and certain traditional peasant dishes became symbols of national styles of cooking. Hungarian *gulyás* (goulash) is a classic example. Originally it was a stew prepared by cattle drovers, herders whose occupation was essentially the same as the gaucho of Argentina and the cowboy of the American West. Their unfettered lifestyle and distinctive eating habits became a symbol of Hungarian identity; thus, the food they ate was elevated to a national icon.

This process occurred in all of the Central European countries and was in many respects random since it overlooked the fact that there were numerous ethnic groups who did not aspire to form states of their own, among them the Jews, Armenians, and gypsies. While the Central European Jews belong to the Ashkenazim, their traditional food culture represents elements of Spanish Sephardic traditions combined with South German flour-based dishes and such Slavic features as borscht or *blinz*.

### Periodization of Culinary History

The food culture of Central Europe may be broken down into historical periods corresponding with the rest of Europe, although, in general, development has lagged behind western Europe. The medieval period lasted until about 1500, followed by a period of political upheaval and consolidation from 1500 to 1680. Ottoman invasions occupied the political stage, and the countryside experienced vast destruction and loss of populations. The era from 1680 to 1850 may be viewed as one of reconstruction and political reorganization under the Habsburg monarchy. Political unification brought with it cultural repression and an institutionalizing of German as the *lingua franca* of the region. In the 1780s all Jews living within the Austrian Empire were forced to Germanize their names. German became such a dominant language that in some regions, such as Bohemia, it nearly replaced the local tongue.

The foods and foodways of medieval Central Europe represent an area of research largely unexplored by scholarship, in part due to the lack of surviving records. Maria Dembińska's pioneering work on medieval Poland (1963) has pointed the way for similar studies of Bohemia and Hungary, but published research is limited. In spite of this, some generalities can be made. The kingdoms of Bohemia and Hungary were powerful in the early Middle Ages, and Bohemia in particular became the epicenter for many culinary influences in the region. Likewise, the Danube River served as a conduit for new foods and dishes emanating from Byzantium. The strudel, the cucumber, and red beets moved into Central Europe by this route. The lack of written records has been addressed through medieval archeology, especially since World War II.

### Meal Systems in Central Europe

The medieval meal systems of Central Europe are key to understanding meal systems of the region, even in the

twenty-first century. Traces of the medieval two-meal system (a light meal in the morning about 9:00 A.M. and an evening meal about 5:00 P.M.) still survive in parts of Central Europe, and this eating pattern defines the type of foods consumed. During the summer half of the year (from spring plowing to fall plowing), field workers eat three times a day, but during the winter they revert to the medieval two-meal system. In grain-growing regions, the first meal eaten in the early hours of the day was generally bread with lard or cottage cheese, since it was easy to transport. A midday meal of hot cooked food was brought to the field hands during their break. In the crescent-shaped mountainous zone surrounding the Carpathian Basin as well as in the Carpathian areas of the Ukraine and Transylvania (Romania), the morning meal was a hot cooked dish, such as Romanian *mamaliga* (corn-meal mush). The midday meal consisted of remnants from the morning, while a cooked evening meal was eaten at home. It was also a general custom to eat from a common bowl. Until the late nineteenth century, children normally stood to eat at the dinner table, and men and boys ate separately from women and girls. Once children reached the age of puberty, they were given a place to sit at the farmhouse table in accordance with their status in the family. For example, younger boys of lesser rank sat lower down the table than their older brothers, who had first choice of the food after their father.

Another unifying feature of Central European cookery is the widespread use of gruels made from hulled, whole, or cracked grains. The grits can also be made from lentils, peas, fava beans, and in more recent times from New World beans. All levels of Central European society ate grits, but the proportion varied. Wealthier people consumed more meat, while the poorest individuals subsisted on an essentially vegetarian diet. In medieval Poland the inevitable gruel for king and peasant alike was millet. In modern-day Romania it is *mamaliga* made from maize. Rice has never played a significant role in the cookery and has always been associated with luxury foods and urban cuisine. Only the Bulgarians grew rice on a large scale, mostly for provisioning the Ottoman army. Rice did not become integrated into Bulgarian food culture until the eighteenth century.

Along with grain-based gruels, bread soup was another universal food throughout the region. This is a dish of medieval origin in which pieces of bread are soaked in hot broth, then puréed, or the broth is simply poured over a slice of bread. Nearly every country in Central Europe possesses a long list of local variations on this theme. More elegant preparations replaced the bread with roux, flour fried in lard or bacon drippings. A close relative of this soup was a dish made from small balls or crumbs of dough produced by rubbing the dough against a sieve or grater. The dough was then boiled in water, milk, meat stock, or vegetable puree until thick. The most typical dish of this kind prepared in Hungary is called *tarbonya*, a term borrowed from Turkish in the eighteenth century.

During the Middle Ages it was called *vágott éték*, *vagdalt éték*, and *gombóta*, terms all referring to the shape of the dough or to the action of rubbing the flour. In mountainous areas of Slovakia, Poland, and Romania, this dish is made with buckwheat flour.

The introduction of maize via the Balkans was perhaps the most important addition to the gruel-based diet of the countryside. In most areas it was first introduced as a fodder crop, but poor farmers in mountainous areas soon adopted it as a foodstuff since it was much easier to grow than wheat. The most common method of preparing it was in the form of mush, but it was also used as a filling in sausages, as dumplings mixed with meat or vegetables, and as a stuffing in steamed cabbage leaves. The mush is known as *mamaliga* in Romania and *puliszka* in Hungary.

### Shifts in Taste Preferences

In terms of general taste preferences, there have been a number of important shifts in Central European diets. Pickled vegetables (especially cabbage and root crops), vinegar preparations, and sour milk are found everywhere, especially in areas where beer is the most common beverage. The sweet-and-sour or tart and spicy foods preserved in peasant cuisine began to disappear in urban cookery during the eighteenth century in favor of more neutral tastes. This shift occurred directionally from west to east and from the upper classes to the lower ones. Sugar at one time represented a prestige food consumed only by the aristocracy and rich merchants, and it reached peasant cookery only in the nineteenth century. The preference for food highly spiced with black pepper shifted in the late eighteenth century to a widespread use of paprika. This shift began in the lower Balkans and emanated out of Bulgaria, where New World peppers had been introduced in the 1600s. The Bulgarians have always been the market gardeners of Central Europe, and it was through them that many new foods, such as beans, maize, and tomatoes, were disseminated into the Slavic regions.

### Drinking Habits

Central Europe can be divided into three large zones according to the predominant drinking habits. The north-eastern region, including the Czech Republic and Poland in particular, are beer-drinking countries. In the north-west, brandy and spirits predominate, while the southern area is largely wine-drinking. The centers of wine production lie in Slovakia, Hungary, and Romania. The Romans introduced viticulture into these countries, and many grape varieties are peculiar to central Europe, among them the famous Tokay of Hungary.

Among the nonalcoholic beverages, buttermilk, whey, and a light beer made with birch sap (*Betula pendula*) were popular in many parts of the region, as were herbal teas, especially medicinal teas made with Saint-John's-wort. Coffee drinking spread from the Balkans

due to Turkish influence. Coffee is consumed with milk as an early morning beverage or is taken black after meals. The peasants first served it at the beginning of feasts and weddings and only later incorporated it into their everyday diet.

### Poland

Poland's culinary history did not begin in 1364 with the famous Congress of Kings held in the ancient capital city of Cracow, but it was during that event that Poland's distinctive cuisine was showcased to the world. The host of this gathering, which included hundreds of nobles and several thousand retainers, was King Casimir III, who had positioned the kingdom as a world power and who was himself a connoisseur of Italian cooking. Present at this congress was Peter I de Lusignan of Cyprus, who brought

Poppy seeds are used extensively in Central European cooking. During the Middle Ages poppy seeds were associated with fasting dishes, but today they are enjoyed in traditional cakes like the one shown here. PHOTO BY ANDRÉ BARANOWSKI.

with him Byzantine cooks, a troupe of gypsy musicians, and eating habits of the East. The culinary watershed of this event has not been studied in great detail, but after that, Polish dishes are mentioned frequently in cookery books of the 1400s and 1500s as one of the recognized “national” styles of cooking. Elements of Poland’s medieval cuisine have also been preserved in the countryside, as the Polish ethnographer Zofia Szromba-Rysowa has pointed out in her study of village foodways *Przy wspólnym stole* (At the common table, 1988).

Poland’s culinary identity may be divided into four broad regional styles: the cuisine of the mountainous south; the cookery of the Baltic coastal region; the foods of the east, principally dishes emanating from Lithuania and Russia; and the classic cookery of the great estates and urban restaurants. The influence of Germany was also pervasive, especially in the period before 1700. The first cookbook written in Polish, the *Kuchmistrzostwo* of 1532, was a translation of a popular German cookbook called the *Kuchenmeisterei* that first appeared at Nürnberg in 1485. The first truly Polish cookbook was published at Cracow in 1682 by Stanisław Czerniecki under the Latin title *Compendium Fercolorum*. Czerniecki was a petty noble who served as royal secretary to King Jan III So-

bieski. Parallel to the German influence was the Yiddish-speaking Jewish community, one of the largest in Europe.

When the elector of Saxony ascended the Polish throne in the early eighteenth century, he brought with him French cooks. This blend of French and Polish themes in the court cuisine of the country helped to create the Polish cookery that has survived into the twenty-first century. Poland’s haute cuisine has always differed from that of other European nations in that it has drawn its inspiration from the peasantry and recreated these foods not only as symbols of Polishness but also as a political reminder that Poland’s most ancient monarchs and noble families were themselves the children of peasants. These dishes include *bigos* (a game stew); the baba cake; *sauce polonaise* (a sauce originally served with boiled pike); and a host of sausages (the Polish word *kielbasa* simply means ‘sausage’), the most famous of which are *kielbasa krakowska* (pressed ham sausage), *kasza gryczana* (buckwheat kasha), and pierogi, the Polish equivalent of Spanish empanadas. Polish beer and vodka are also well-known outside the country.

### The Czech Republic

Although small in size, the Czech Republic is one of the wealthiest and most industrialized of the Central European countries. It is also blessed with a rich culinary history tracing back to the early Middle Ages. The country consists of two major regions, Bohemia and Moravia, each with its distinct local cooking style. The capital, Prague, is situated on the Vltava River, which flows north into Germany. This geographic link brought the city and its culinary culture in constant contact with German Saxony and the Baltic port city of Stettin at the mouth of the Oder. However, due to its political domination by Austria, Prague became a melding place for many exotic culinary ideas and the location of a number of well-known cooking schools and restaurants. Prior to World War I, the company of Bohuslav and Vydra was internationally known for its culinary equipment, especially gingerbread and pastry supplies. In the area of pastry, the Czech Republic is perhaps best known as the home of the layer cake (torte) and *koláče* (sweet buns with a variety of fillings). Both terms evolved from Latin.

Other important culinary centers in the country are Karlovy Vary (the former Karlsbad), which was a famous spa resort during the Austro-Hungarian Empire, and Plzeň (Pilsen). Plzeň is a scenic town noted for its Pilsner beer. Until 1945 the town was situated in the heartland of the Sudeten German region. After the expulsion of the Germans, the Czechs continued the famous brewery and maintained an international standard for high-quality brewing.

As a counterpoint to the heavy Germanization of the country under the Austrians, Bohemia produced Magdalena Dobromila Rettigová (1785–1845), a cookbook writer whose recipes were widely circulated in Czech and

Polish family in Upper Silesia enjoying a dessert course of traditional homemade cakes and fruit wines. PHOTO BY ANDRÉ BARANOWSKI.

were translated into German. Rettigová also wrote juvenile literary fiction that championed the national language. She was followed by Božena Němcová (1820–1862), whose semiautobiographical novel *The Grandmother* (1855) described the foods and daily life of Bohemia and offers a detailed look into the mind-set of a culture besieged by foreign and mostly Germanizing influences with a long list of foods the author considered typical of Czech culture. Some of this nostalgia for the past is present in Marie Rosická's *Bohemian-American Cook Book* first published in Omaha, Nebraska, in 1915. In print off and on since its first appearance, the book is an important culinary link to the homeland for Czech immigrants in the United States.

### Slovakia

While Slovakia speaks the same language as the Czech Republic, it has experienced a different history. The an-

cient capital city of Pressburg (now Bratislava) on the Danube has oriented the country southward, and for much of its history Slovakia was a territory of the kingdom of Hungary. Like Hungary, Slovakia is a wine-growing region, thus it forms a cultural line of demarcation between the beer-drinking Slavs to the north and the wine-drinking central Europeans to the south. The country's wines are mostly white, consisting of Pinot Gris (Rulandske to Slovaks), Sylvaner, and a few others. The main wine-growing area centers around Modra, north of Bratislava.

Slovakia is also a country where fish play an important role in the diet, especially trout and carp. During the Middle Ages, Slovakian towns along the Danube were involved in an extensive fish-pickling industry, once critical to the Roman Catholic dietary calendar. Since it lay on trade routes with Poland and Bohemia, Slovakia also served as a conduit for culinary ideas flowing out of

Hungary and the Ottoman Empire. Maize is significant in the diet, and Hungarian *gulyás* is prepared in myriad ways. The Carpathian Rocombole garlic, popular among American growers, came from the eastern part of this country.

### Hungary

Most food historians do not realize that Marcus Rumpolt, the author of *Ein New Kochbuch* (1581), was Hungarian by birth, not German. While his cookbook is viewed as a classic of German Renaissance printing, a number of the recipes incorporated in the book are Hungarian. The book was also translated into Hungarian. Rumpolt is just one example of the pervasive influence Hungary has had on the cookery of Central Europe. On the international level, Hungarian cookery is perhaps the best-known of all the cuisines of Central Europe, and so are its wines.

Hungary experienced the fate of being a great medieval power, only to suffer defeat and invasion by the Ottoman Turks. The medieval kings of Hungary enjoyed a long association with Italy, especially southern Italy and Sicily, thus Hungarian cookery early developed a distinctiveness best characterized as a blend of Slavic and Mediterranean Europe. The Turkish occupation of the country devastated it, and not until the 1680s were the Turks driven back, after their defeat at Buda. Through dynastic marriage, the kingdom of Hungary became part of the Habsburg Empire, but Turkish influences lingered and blended with local culinary traditions, coffee drinking among them. However, Austrian rule meant that both upper-class and middle-class cooking became heavily Germanized. Many of the foods associated with Hungarian cuisine came from the countryside, among them *pörkölt* casseroles, *gulyás*, *palacsuták* (a type of pancake), and *Liptó* cheese made with goat milk.

In contrast to this, Budapest became a great center for pastry baking, in part due to the proximity of wheat-growing districts and constant contact with the Viennese court. Two of the best-known nineteenth-century cafés were Gerbaud's in Pest and Russwurm's in Buda, but the most famous of all was run by József Dobos, whose Dobos Torte is found in every cookbook devoted to elaborate cakes.

Nothing about Hungarian cuisine, however, is better known than paprika. Introduced in the eighteenth century from Bulgaria, paprika gradually made such inroads into Hungarian cookery that it became a defining element. The Hungarians have also become the unrivaled masters in pepper breeding, so in any given farm market it is possible to see vast quantities of unusually shaped peppers, both sweet and hot, piled in heaps or hanging in endless strings among braids of garlic and other local produce. Hungarians enjoy peppers with every meal, even at breakfast. One popular breakfast dish consists of hot peppers stuffed with bacon drippings. The peppers are sliced and eaten on rye bread.

### Romania

Romania's borders have moved considerably throughout history. The western part of the country was once the Principality of Transylvania and part of the Austro-Hungarian Empire. It is difficult for a country that speaks a romance language to look west toward Vienna for culinary inspiration when it has the Black Sea lapping at its feet. This mixture of Slav and Latin, of Orientalism and self-conscious Francophilia, characterized the flowering of Romanian haute cuisine during the interwar period. It was the product of literati, and it was decidedly sybaritic.

This is not the Romanian cookery of modern cookbooks, yet in reality there are probably two distinct Romanian cookerries, one created exclusively in the restaurants, an important aspect of Romanian social life, and the simpler foods made at home. Much unites both of these cookerries with the Mediterranean and the Near East. Spit-roasted meats, stuffed vegetables, rice pilafs, an abundance of eggplants, and a good array of local red and white wines all work together to give the food a peculiarly Romanian character. Food is often served *mezze* fashion, in an array of small dishes, and there is a widespread preference for hot pepper.

*Mamaliga*, Romanian polenta, is well-known and has already been mentioned, but not as well-known are Romanian *ghiveci* (a dish resembling ratatouille), *mititei* sausages (garlic-flavored beef sausages), carp's roe paste (*icre*), sour winter soups, and *sarmale* (stuffed cabbage leaves). In Transylvania the cookery changes due to the presence of a large German minority that settled there in the Middle Ages and to an even larger Hungarian community. Both of these groups have distinctive local cuisines that have had an important influence on Slovakia and Hungary to the west.

## CEREAL GRAINS AND PSEUDO-CEREALS.

Cereals and pseudo-cereals are the primary carbohydrate supply for the world's human population. Nearly half of the annual cereal production is used for human food. Cereals also serve as the primary food for dairy and draft animals, poultry, and wild birds, and are the main ingredient in the production of alcohol. The primary cereals include wheat, rice, corn, sorghum, millets, oats, barley, and triticale. Wheat and rice provide nearly 50 percent of the world's food energy. Millet is a term that refers to small-seeded grain and has been applied to many unrelated species. The primary millet involved in world trade is proso millet, which is grown mostly in northern China. Foxtail millet and pearl millet, totally unrelated species, are also widely grown for grain on subsistence farms in Asia and Africa, respectively. Three other unrelated millets—finger, brown-top, and Japanese—are locally important cereals on subsistence farms throughout the world. Pseudo-cereals include amaranth and buckwheat.

### Defining Cereals and Pseudo-Cereals

Cereals are members of the grass family (Gramineae) that are grown for their edible starchy seeds. Pseudo-cereals are grown for the same purpose, but are not members of the grass family. Since they are grouped based on use rather than the biology of the plant, this aspect will be considered separately. Initial development of cereal plants involves seminal roots that vary from three to eight in number. They arise directly from the hypocotyl. Further plant development includes the development of a second set of roots which are permanent and arise from the point just a little below the surface of the ground. These roots are fibrous rather than tap and are noted for their ability to control soil erosion through an extensive network of root hairs. They extend outward and downward in all directions from the crown, providing the primary nutrition for the plants.

Cereals are identified by alternate two-ranked leaves that are frequently formed near the ground. The leaves are composed of a sheath that encloses the stem (culm) and is split down the side opposite the blade. Identification of vegetative plants is usually based on the shape and size of the ligule, which is an appendage extending upward at the juncture of the sheath and the blade, and on the presence or absence of hairs in this region. The stems are composed of nodes and internodes that elongate to

varying degrees as the crop matures. The nodes associated with leaf blades are the most apparent and are identified as the swelling in the stems. Nodes lower on the plant have the potential to develop additional stems, which are frequently referred to as tillers. The grain is produced on a spikelet that varies significantly from corn to wheat to millet in size, shape, and appearance.

The cereals and pseudo-cereals are essentially a starchy crop. However, they may contain significant quantities of protein and oil, and it is frequently these constituents that determine suitability for a specific end use. Structurally the seeds are composed of three main parts including the endosperm, embryo, and seed coat. The endosperm is the primary starch storage portion but also contains some protein. The embryo is the oil storage portion, high in protein and minerals. The seed coat, also called pericarp or bran, consists mainly of cellulose and hemicellulose with some protein and lignin. Relative proportions of the three components vary among the different cereals with the embryo of "small grains" such as wheat and barley making up less than 4 percent of the total seed, while in corn it averages 12 percent. There is also large variation from variety to variety.

Buckwheat and amaranth are two of the most widely used pseudo-cereals, but their production is dwarfed by the true cereals. Buckwheat is in the Polygonaceae family and amaranth is in the Amaranthaceae family. Neither has been the primary energy source for large regions, but both have played significant roles in food use. They both have a tap root rather than a fibrous root system and have two cotyledons rather than one as is true for the grasses. The root system consists of a tap root (central or primary root) that extends downward to a considerable distance. This root is thicker and stouter than the lateral roots that arise from it. The lateral roots may be divided several times. The tap root first penetrates the soil for some distance, forming no laterals. Laterals are then formed, beginning at the upper portion of the tap root. Buckwheat and amaranth are herbaceous, erect growing annuals. Under ordinary conditions buckwheat attains a height similar to wheat. Amaranth is typically twice the height of wheat, but there are some dwarf varieties that seldom grow taller than four feet. Both plants adjust themselves very efficiently to surroundings, such as fertility of soil and rate of seeding, by sending out branches from the main stem. The buckwheat kernel is in the form of an achene, being a single seed enclosed in an indehiscent pericarp that fits tightly around the seed. The achene is three-angled, the angles being acute, and has the form of a pyramid with the base rounded. The hull or pericarp varies from silver gray to brown or black in color and is hard and thick, with the surface polished and shining. It separates readily from the mealy endosperm. The relatively large embryo is central, dividing the soft, white endosperm into two parts, the cotyledons being broad. The surrounding testa is membranous and light yellowish-green in color.

Buckwheat groats, called kasha, are sold in whole and granulated form. Kasha can be baked, boiled, or steamed to serve as an alternative to rice and potatoes. Buckwheat flours have been used extensively in pancake mixes as well as in various breads. The Japanese mill buckwheat groats into flour for use in the production of soba noodles, a major part of the Japanese diet. Buckwheat flour is the primary ingredient in such European dishes as polenta and Zganci.

Reliance of the world population on one or more of the cereal grains as a primary food material is not just happenstance. They contain the main food essentials for the human and animal body, although they are deficient in vitamins and may be low in particular amino acid portions of the protein. Pseudo-cereals frequently have a unique amino acid profile and can be used to supplement cereals for a more balanced amino acid diet. Starch, the primary constituent of cereal grains, breaks down in the digestive tract into simpler and more easily digested sugars to supply the body with its primary source of energy. While varying in oil percentage, the oil plays a significant role in total energy supply in the diet and some varieties have been selected with amounts adequate for processing and selling as vegetable oil.

While rich in thiamine, riboflavin, niacin, and pantothenic acid, the cereals do not meet all of the vitamin and mineral requirements for food or feed. Frequently foods and feeds that are used to supplement these needs are considered more important than the cereals themselves, but as a proportion of total food and feed consumed, none come close. The role of fiber in the diet has recently been studied extensively and has altered somewhat the thought on the value of the seed coat, which contains the highest portion. This portion is also high in vitamins and minerals and many recipes have been altered to include higher proportions of whole grain or bran to take advantage of the health benefits.

Cereals and pseudo-cereals are not often used as human food without some preparation to convert them to a more edible and digestible form. Modern processing methods utilize grains to produce everything from tortillas to macaroni, as well as breakfast food, flour, bread, and vegetable spreads.

### Origins of Cereals

The origins of some cereals are obscure. More than one had its cultural beginning before recorded history. The development of cereal grains, probably more than any other factor, permitted the earliest tribes to change from nomadic life to full or partial agricultural subsistence. They provided more food with less effort than did any other crop. They were important for their ability to provide subsistence and security of subsistence over time. Cereals can be easily stored to provide food between harvests. Their role in reducing the time spent by people in hunting and gathering allowed humankind to develop other pursuits.

The various cereals probably developed in different parts of the world. Corn is likely the only cereal native to the Americas, while wheat and barley may have been cultivated first in the Fertile Crescent area of the Middle East. The pseudo-cereal amaranth is also native to the Americas, and the earliest identification of amaranth as a grain comes from archaeological digs at a cave in Tehuacan, Puebla, Mexico, where seeds of *Amaranthus cruentus* were dated as six thousand years old. Aztec writings are the first recorded indication of its use and mention collection of large quantities of amaranth along with corn and beans in annual tribute to the ruling class. Although the origin of proso millet has not been ascertained, it is one of the first cultivated cereals, most likely prior to wheat. Proso millet has been known for many thousands of years in eastern Asia including China, India, and Russia. The genus *Setaria* is widely distributed in warm and temperate areas. Foxtail millet, the most widely grown food of this genus, is one of the world's oldest cultivated crops. Its planting was mentioned in Chinese records as early as 2700 B.C.E. Foxtail was the most important plant food in the Neolithic culture in China, and its domestication and cultivation constituted the earliest identifiable manifestation of this culture, the beginning of which has been estimated at over four thousand years ago. Buckwheat is native to temperate east Asia, where it was grown in China before 1000 C.E.

### Modern Cereal Production

Development of mechanization for planting, harvesting, shipping, and processing of cereals during the first half of the twentieth century led to the greatest advancement in cereal production since the dawn of history. Practically all labor involved in modern cereal production involves mechanized operation. Mechanization—along with improvements in weed, disease, and insect control, improved nutrient management, and variety improvements—increased production potential and led to the Green Revolution in the second half of the twentieth century. Today, one farmer typically provides cereals that feed more than one hundred people. The average yield per unit of land of cereals has increased by more than 50 percent in the last fifty years. Increases in corn and rice have been more dramatic than those of the other cereals, but all have shown steady improvements. The dramatic yield improvements in corn have led to a production area increase in corn at the expense of oats, millet, rye, and barley. Especially in China, millet production has been pushed to more marginal areas with the best land being dedicated to corn and rice, with higher yield potential.

The sickle or reaping hook was used for cutting cereals during the Stone Age. In biblical times the blades were made of bronze or iron. Steel sickles were made in the nineteenth century. The sickle is still a part of harvesting in many developing countries. Typically a man with a sickle can cut, bind, and shock an acre of grain in

around forty hours. A scythe was more common in the Roman Empire and areas of the Orient. With attached cradle frames, harvesting time was cut to twenty hours per acre. In the first century of the common era, Pliny the Elder described a grain stripper that was pushed by oxen and used by inhabitants of Gaul. Between 1775 and 1840 reapers were developed in Europe and the United States, but this was quickly replaced by combines by 1950. The combine not only replaced the reaper, but also replaced the thresher that was developed in the latter half of the nineteenth century. Before then, grain had been flailed out by hand or threshed by treading out the grain under the feet of people or livestock. With a flail a man can thresh seven or eight bushels per day. A form of threshing machine still used in Asia and Africa consists of stone-studded planks, stone rollers, or metal disks on a shaft drawn by animals over the grain stalks that are spread on a threshing floor. Today, modern combines cut, thresh, and clean more than one hundred acres per day.

The mechanical corn picker was not developed until World War II and replaced the age-old tradition of husking by hand from the standing stalk. If the stalks were being harvested for forage, some cut them by hand and placed them in shocks to cure. Today the corn picker has been replaced by the modern combine used on other small grains with only modifications of the header.

### Storage and Transportation

Compared with many other crops, cereals and pseudo-cereals are extremely amenable to storage. The moisture content at harvest is typically below 15 percent and their composition and seed coats are such that deterioration is slow. Seasonal harvest with a continuous demand means that storage between harvests is required. Under typical conditions this need can be met easily; with care, storage for many years without serious loss of quality is possible. Storage during times of surplus is a part of human history, and with benefits of modern technology, cool dry conditions can be maintained and storage can be successful for extended periods of time. There are, however, problems with storage, including excessive moisture content at the time of storage, excessive temperature, microbial, insect, and arachnid infestation, rodent and bird predation, mechanical damage, and biochemical deterioration. The latter is especially important for cereals and pseudo-cereals with higher than normal oil content because the oil becomes rancid over time.

The distribution system for cereals is frequently criticized as there is a surplus of production and yet hungry people around the world. However, the infrastructure that moves cereals by truck, train, barge, and ship is one of the most complex and efficient systems in the world. It is estimated that rail shipments from Kansas and Nebraska—the heart of winter wheat production—to the Pacific Coast, or a combination of truck and barge shipments to the Gulf Coast, cost less than \$0.50 per bushel, including less than \$0.15 for transportation from the field

to a local destination, and that loading on a ship and delivering to a handling facility in Southeast Asia or Africa adds only \$0.50 per bushel. Getting from one village of the developing world to the next can double the total value of the wheat.

### Processing

Cereals are processed in many ways, but the methods are broadly grouped into wet milling, dry milling, oil processing, fermentation, and feed processing. Characteristic features of milling processes include separation of the endosperm from the embryo and seed coat, and reduction of the endosperm into flour or grits. Milling schemes are classified as wet or dry, but this is a relative classification because water is used in almost all separations. Few generalizations can be made about cereal milling. For example, most rice is milled in two stages to remove the husk and then the bran, however, some is milled into flour. There are dry milling processes that change the shape and size of cereal. Fractions produced by this step are frequently separated in another step. An additional milling process can be completed by changing the temperature or water content. Unlike dry milling, which primarily just fractionates, wet milling is a maceration process in which physical and chemical changes occur in the basic constituents: starch, protein, and cell wall material. The objective is complete dissociation of the endosperm cell contents with the release of the starch granules from the protein network. Processing has taken a huge step from Stone Age grinding stones for dry milling to soaking processes to remove starch, described by Cato in the second century B.C.E., to modern milling and extrusion processes. Milling processes today are almost entirely based on meeting end product specifications by the most efficient means possible with almost all steps controlled mechanically and electronically.

The other primary processing method is production of alcohol from cereal grains through a fermentation process. This two-step process includes the conversion of starch to soluble sugars by amylolytic enzymes, followed by the conversion of the sugars into alcohol. In the first step the enzymes may be derived from the grain itself (malting), from other organisms present or added as extracts. The malting process has also been used for the production of some breakfast foods. It is comprised of a controlled germination during which enzymes capable of catalyzing hydrolysis of starch are produced. The fermentation process results in the development of alcoholic drinks, including beer and sake. Further processing by evaporating and condensing increases the alcohol content and produces whiskey, scotch, bourbon, and neutral spirits, including those used for production of fuel. Today production of gasohol ranks as one of the largest uses of corn following its use as animal feed. The by-products of fermentation are primarily used as livestock feed.

The number of foods prepared from a base of cereals is the largest of all food crops. Cereal grains are largely

interchangeable for different uses and are, therefore, mutually competitive. They can substitute for one another in a number of food and nonfood uses. In their use as feeds they are almost completely interchangeable. That allows more latitude within which available grain supplies can satisfy a series of demands.

As raw materials in major processing industries, however, grains are not always so interchangeable. Technology of a particular process often requires a specific combination of chemical and physical characteristics in the raw material, which can be met fully by only one type of grain. This has been extended to variety specificity for many products and has led to the development of identity-preserved marketing systems that are quite distinct from the bulk transportation systems discussed earlier. Some predict that with greater use of biotechnology for adding trait specificity, the identity-preserved marketing systems may become increasingly important.

Cereal uses for food are largely defined by cultural context, but with the greater global movement of people, there is now a greater dispersion of foods. For example, rice-based products are now a common food item in places with no rice production. The same is true of amaranth.

The Aztecs used amaranth, which they called *huautli*, in a beverage, a sauce, for a type of tortilla, and for various medical uses. Popped or ground amaranth often was mixed with honey or other sweet, sticky plant materials, and then shaped into a variety of figures and shapes that were used in celebrations and religious ceremonies. Unlike most cereals, amaranth leaves are used as a vegetable, similar to spinach, and certain types have been selected almost exclusively for their leaf production. Most commercial production of amaranth is for types selected primarily for grain or forage production.

Both cereals and pseudo-cereals have a long history of use as forage crops for livestock. The small grains have been used extensively for hay, grazing, green-chop (fresh fodder harvested and used as cattle feed), and silage. Foxtail millet, pearl millet, and some other millets are perhaps better known for their forage use than for their grain production. Corn and sorghum are utilized extensively for silage. Almost all stover of all cereals and pseudo-cereals has potential utilization by livestock even though it may require supplementation with higher-protein feeds. Prior to the soft dough stage, when the kernel is still immature and has not yet hardened, most cereals meet or exceed nutrient requirements of livestock. Cereal forages are used as supplemental feed for cow and calf herds, support major elements of the stocker cattle industry, and have potential to produce finished beef. Cereal improvement programs, while directed at improved seed production, have improved disease resistance, stress resistance, insect resistance, and general adaptability to specific climates. This has led to significant improvements in consistency and quantity of forage production as well.

Cereal silage is an important part of the dairy industry. Corn silage alone makes up over 40 percent of the value of the forage fed to dairy cows in the United States. Corn silage is noted for its palatability, consistent quality, high yields, and energy content compared with alternative forages. The cost of production tends to be lower for corn silage than for most other forages, but this is partially offset by the large transportation costs of relatively wet material. Transportation costs have largely limited use to livestock production near the field from which the silage was harvested.

While the cereals and pseudo-cereals are primarily known as a source of energy, they have played important roles in other ways throughout history. Cereal sprouts have long been known for their cleansing properties and are a common part of health food stores. Amaranth and buckwheat have been evaluated extensively for their vitamin E, B<sub>1</sub>, and B<sub>2</sub> activity in reducing arteriosclerosis. Oats and buckwheat are recognized as cholesterol-lowering foods. The pseudo-cereals have a different amino acid composition than the cereals and when combined in the diet produce a much more ideal amino acid balance.

Perhaps because of their importance in meeting daily sustenance and perhaps for other reasons, the cereals have been a symbol of human life and culture throughout recorded history. Amaranth played a major role in pagan rituals. Wheat and wheat harvesting are a part of world symbolism from the flags of major countries to churches and cemeteries. So much emphasis was placed on grain production by Roman peoples that the protection of grain was the primary concern of Ceres, one of the powerful Roman goddesses. The name cereal was derived from this association. With the huge supply of human energy coming from a few major cereals, and a few minor cereals in some regions, one of the big concerns for the world population is the risk of a major crop failure. This possibility has received increasing attention as selection and major gene improvements have narrowed the genetic base within crops to a few major varieties. It is particularly important that the diversity within major crops is conserved effectively, available for use, and managed wisely.

**CEREALS, COLD.** Cold cereal has been a favorite breakfast of millions of Americans for several generations. Ready-to-eat cold cereal started as a healthy snack in the early 1900s. By the twenty-first century more than 2.7 million pounds of cold cereal were consumed by children and adults each year in the United States.

Cold cereal makes a quick, nutritious, low-cost, and portable breakfast. Ready-to-eat cereal products supply important nutrients. When combined with low-fat milk, cold cereal makes a meal that is high in protein and low in cholesterol and fat. Milk and grains compliment each other nutritionally since they are from different food

groups. Most cereals are fortified with at least 25 percent of the daily recommended intake of essential vitamins and minerals and may provide up to twenty-six grams of fiber per cup of cereal.

Hot, cooked grains started long ago, but cold, ready-to-eat cereals were not available until Will Keith Kellogg and his physician brother John Harvey Kellogg began experimenting with flaked wheat in the early 1900s in Battle Creek, Michigan. While John Harvey Kellogg sought a nutritious food for his patients, Will Keith Kellogg recognized the sales potential of the crunchy, flaked grains that offered taste and convenience. Based on their experiments, Will Keith Kellogg founded the Battle Creek Toasted Corn Flake Company, later renamed the W. K. Kellogg Company. He is credited with transforming American breakfast habits and pioneering the mass advertising campaign in the United States. Competition among cereal manufacturers spurred marketing creativity. Cheerios, developed and marketed in 1941 as Cheerioats, supplied World War II soldiers with Yank Paks, special one-ounce packages available to the military. Cheerios also sponsored the *Lone Ranger* radio and

Most cold breakfast cereals are eaten with milk, but the addition of fresh fruits, nuts, or raisins is also popular. © ARTHUR BECK/CORBIS.

television shows during the 1940s and 1950s and featured premiums, such as deputy badges.

Cold cereal has gone through many changes since the Kellogg brothers' time. Most cereals are made from one grain or a combination of several grains, including wheat, corn, rice, oats, and barley. Ready-to-eat cereals fall into three main categories: whole grain, enriched, or restored. Whole grain cereals include the bran, germ, and endosperm—parts of the grain or “seed”—and the nutrients they naturally contain. Enriched cereals contain grains supplemented with vitamins and minerals above the level found in them naturally. For example, most grains are low in vitamin D, so enriched cereals have added vitamin D to meet the body's requirement. Restored cereals contain whole or refined grains plus nutrients that were lost during processing, such as B vitamins and iron. Some cereal manufacturers add 100 percent of the recommended daily value of nutrients; most add just 25 percent.

Experts disagree on the value of cold cereal. Some nutritionists feel that unfortified, natural whole grains are healthier than prepared cereals made from fortified, refined grains. Others argue that consumers are likely to eat more of the sweet-flavored cereals and therefore will eat sufficient quantities to meet dietary requirements. But

cold cereals have more than vitamins and minerals. Fiber is an important part of whole grains and of the human diet. Cereal ingredients such as oats, wheat, and psyllium, contain fiber and help reduce the risk of heart disease. Scientific research indicates that a diet including wheat bran may help reduce the risk of colon cancer.

Cereal boxes note that “diets rich in whole grains and other plant foods and low in total fat, saturated fat, and cholesterol, may help reduce the risk of heart disease.” When shopping for cold cereal, read the nutrition facts on the box. Most nutritionists agree that the best cold cereal contains one or more whole grains, no partially hydrogenated oils, no added sugar, no added salt, and plenty of fiber (at least 3 grams of fiber per 100 calories or 3 to 5 grams of fiber per 1-ounce serving). Some cereal makers add BHT or other artificial ingredients to preserve flavors. Other companies avoid artificial ingredients and depend instead on heat processing at low temperatures or the addition of oil to preserve cereal quality.

Responding to customer concerns, cold cereals are likely to begin to include more plant-derived ingredients, such as cornstarch or herbal blends. Cornstarch helps keep cereal flakes crunchy in milk and helps hold together clusters of fruit, nuts, and grains. Some consumers want their breakfast cereal to supply herbal extracts, such as gingerroot, elderberries, or green tea, as well as whole grains. Look for nontraditional cereal grains, such as triticale, spelt, kamut, quinoa, flax, and soybeans. Sprouted grains offer a sweet, maltlike flavor. Substitutes for refined sugar include honey and fruit-juice concentrates; however, these ingredients add sugar, too. Cereals have also become more portable for on-the-go consumers without the time for a sit-down breakfast.

Patricia S. Michalak

**CHEESE.** Cheese, which has been described as “milk’s leap toward immortality,” can be more dispassionately defined as a product of milk fermentation. Yet part of our fascination with cheese may come from the sheer number and diversity of cheeses worldwide. They number into the thousands, although an exact count is difficult, as cheeses are notoriously difficult to classify. A classification of cheese only in terms of bacteriological processes neglects the symbolism of ancient mythologies, regional pride, and artistic ingenuity that are embedded in this, one of the simplest and most complicated of foods. The mythology of cheese is shared by disparate groups: the Greeks gods and mortals, the conquerors and conquered of the Roman Empire, a delighted Napoleon and the waitress who first served him Camembert. The legends are compelling, but not as much as the product itself.

### History

The beginnings of cheesemaking are unknown, but it has been generally reasoned that the knowledge of how to turn milk into cheese closely followed upon the domestication of lactating animals. Some of the earliest archaeological evidence of cheesemaking comes from the Fertile Crescent, where animals were domesticated around 8000 B.C.E. A Sumerian relief (c. 3500–2800 B.C.E.) portrays cattle and dairying practice. Pots that had likely contained cheese were discovered in the tomb of Horus-aha, the second king of the Egyptian First Dynasty (c. 3000–2800 B.C.E.). And perforated bowls (c. 3000–1000 B.C.E.) made from pottery or rushes have been found in more than one European location. These bowls were designed to drain the liquid whey from the solid curds.

Cheesemaking was an efficient means of preserving an extremely perishable food (milk) from the spoiling effects of the Near East climate. The art and science of cheesemaking spread into Europe, and quickly became a regular part of the diet and a symbol of strength in ancient Greece, where Olympians trained on diets of cheese. Polyphemus, the brutal Cyclops of Homer’s *Odyssey*, milks his animals amid the racks of cheese in his cave, while Odysseus watches quietly nearby. According to Greek mythology, the knowledge of cheesemaking was a gift to mortals by the gods of Mount Olympus. Roman soldiers carried cheese rations with them as the Roman Empire grew, though cheesemaking was highly developed in the Celtic parts of Europe. The Feast of Imbolc (2 February) was a celebration of the approach of spring: the new lambs and the milk of the ewes represented the changing seasons and were honored as a first sign of spring.

Artisanal cheesemaking might have been lost after the fall of the Roman Empire if not for the Christian monasteries. The monks not only preserved cultural traditions during the Dark Ages, but spent much time reworking and improving cheese recipes. Their creations,

among them French Munster and Epoisses, are still referred to as “monastery” or “trappist cheeses.”

In the following centuries, cheesemaking grew as an art and industry. The first commercial cheese factory in the United States was established in Rome, New York, in 1851. Innovations like the kind of cream cheese popularly known as Philadelphia Cream Cheese and pasteurizing whole cheese (patented in the United States by James Kraft in 1916) followed. Almost a century of pasteurized process cheese sales in the United States and abroad have demonstrated their popularity, but a growing number of cheesemakers and cheese-eaters are committing to the preservation and production of artisanal (made by hand) and farmstead (made from the animals of a farm on that farm) cheeses. Several books about specialty cheeses have been published in the last few years, and wider selections of domestic and imported cheeses are available in supermarket, and restaurants.

### Milk

When confronted by the vast number of cheeses, the different shapes, colors and aromas at a well-stocked cheese counter, it is astonishing to remember that all these endless varieties come from only one basic ingredient. Although a cheesemaker makes many decisions throughout the cheesemaking process that will affect the finished product, the first step is always to select the raw material, milk.

Cheese can be made from any animal that produces milk: cow, sheep, goat, camel, mare, buffalo, or yak. With the exception of Italy’s mozzarella *di bufala*, made from the milk of herds of water-buffalo, cheeses in the Western world are typically made from the milk of cows, goats, and sheep. Of the three animals, sheep produce the lowest volume of milk, but because it is so much higher in fat and protein content than either goat’s or cow’s milk, less of it is needed to make cheese. On average, ten pounds of cow’s or goat’s milk or about half that amount of sheep’s milk is required to make one pound of cheese. In contrast to the rich, concentrated flavor of sheep’s milk, goat’s milk is slightly sweet and fresh-tasting; cow’s milk is the lightest of the three. The milk of individual breeds of the same species also has a unique flavor profile. Consequently, the laws governing many name-controlled cheeses specify the breed of animal from which the milk is to come. Cheesemakers have the further choice of how to use the milk they collect: full fat, partly skimmed, or with extra cream added.

Free-grazing animals feast on a bounty of wild grasses, flowers, and other vegetation during the warmer months. This gives their milk a complexity of flavor that is easily distinguishable from the milk of grain-fed animals in winter. Some cheesemakers insist that they can

perceive slight flavor adjustments daily—as the animals move from one pasture to another.

### Pasteurization

Milk used for cheese may or may not be pasteurized. Pasteurization is a process of heating milk that destroys most of the naturally present bacteria (see Cheese Safety below). Current U.S. law requires that cheeses be pasteurized or, if made from unpasteurized milk, aged for at least sixty days at 35°F before sale for consumption. Milk may be pasteurized in one of two ways: by heating it to 161°F for fifteen seconds, or by heating it to 145°F for thirty minutes (the latter method is sometimes called “heat treatment”). These laws apply to both domestically produced and imported cheeses. When cheese is made from unpasteurized milk, it is frequently referred to as “raw milk” cheese, connoting that the milk has not been

“cooked.” Most cheesemakers believe that the brilliant nuances of flavor found in raw milk, with its naturally present “good” bacteria, simply cannot be duplicated in a pasteurized milk cheese, though some well-respected cheeses, including British Stilton, are made only from pasteurized milk.

### The Principles of Cheesemaking

An oft-repeated legend has it that the first cheesemaker fell into the role by accident. A nomadic tribesman prepared for a long desert journey, he carried a bag made from the dried stomach of a young sheep and filled with milk. As he walked steadily under the relentless sun, the milk began to curdle. Noting that this “fresh cheese” had a pleasant taste and did not spoil as easily as milk, the nomad later drained off the whey and salted the curds to enhance these qualities. The cheesemaking tradition had begun.

While modern cheesemaking techniques are more refined and recipes have become standardized, the basic principles remain the same now as when the (possibly apocryphal) nomad of cheese legend opened his sheep’s stomach bag (which supplied the coagulating rennet), warmed by the sun and agitated by his rhythmic trek.

### The Steps of Cheesemaking

There are as many recipes for cheese as there are cheeses, but all of them follow some combination of these steps.

**Acidification: *souring the milk.*** The milk is gently warmed to encourage the growth of lactic acid bacteria, *Streptococci* and *Lactobacilli*. These bacteria feed on the milk sugar lactose, changing it to lactic acid. As the acidity rises, the solids in the milk (casein protein, fat, some vitamins and minerals) clump together, forming curds in the watery whey (milk is approximately 85 percent water). This is the first step for making all cheeses; in ancient times, cheeses were most likely the result of leaving pots of milk to sour naturally in the sun, affected by bacteria in the air. Some cheesemakers still wait for these process to begin with free, airborne lactic acid bacteria, but most use a starter culture. Starters are widely available commercially, but cheesemakers can also use a bit of the previous day’s milk (unless it is pasteurized)—the same principle as with a sourdough bread starter.

**Renneting: *coagulating the curd.*** Cheesemaking has been referred to as “controlled spoiling” because of the need to efficiently form curds before undesirable bacteria cause the milk to become rancid. The enzyme rennin, traditionally removed from the stomach lining of a young animal (usually the same species of animal that supplied the milk), hastens and completes the curdling process. The renneting property of some plants has been recognized nearly since the dawn of cheesemaking; these vegetable rennets are the traditional agents in several

cheeses. Other vegetarian rennets, made from a yeast or fungus, are also used today.

The curd is left to “set,” forming a network of protein that traps the other milk solids inside. As the solids bind more tightly together, they begin to push out the liquid whey, a process the cheesemaker may continue by cutting, cooking, and pressing. The whey is sometimes used to make cheese as well (Italian ricotta and Cypriot hallumi are two examples), but usually it is discarded.

**Treating the curds.** After renneting, cheese recipes diverge. Some soft cheeses, like fresh goat’s milk cheese, are gently transferred to molds. The curd’s own weight will continue to press out whey. These cheeses might be labeled “hand ladled” to indicate that they were created using this time-consuming method. The Greeks called the molds that held the curds *formas*, which became the root for cheese in Italy (*formaggio*) and France (*fromage*). Our English word “cheese” has its root in the Latin *caseus*, which became *Käse* in German and *queso* in Spanish.

In contrast to the light touch required for soft cheeses, which derive their creamy texture from a higher water content, the curds for other cheeses are sliced and chopped, by hand or machine, to release more whey. The smaller the curds are cut, the firmer the resulting cheese. Cheddar and some other cheeses undergo a unique process called “cheddaring,” which results in its firm, flaky texture. Blocks of curd are stacked, turned, and restacked to press out as much whey as possible. Then the dry curds are milled, ground into tiny pieces, and packed into molds.

Some hard cheeses are “cooked,” that is, the curds are reheated during processing. This causes the curds to release even more whey and alters the texture of the cheese. Examples of cooked cheeses include Emmentaler, Appenzeller, and Gruyère.

**Preparation for aging: salting, molding, and pressing.** Cheeses can be salted in four different ways. For some cheeses, the salt is stirred directly into the curd. A second method involves rubbing or sprinkling dry salt onto the rind of a cheese. This helps to form the rind, protecting the inside of the cheese from ripening too quickly. Some large cheeses are soaked in a pool of brine. The fourth option is to wash the surface of the cheese with a brine solution. In the case of washed-rind cheeses, the salt does not protect the cheese from bacteria—it invites them. The cheeses must be regularly rubbed with water, brine, or alcohol to encourage the growth of the bacteria that give them their sticky orange rinds and distinctive aroma.

Cheese is then transferred, if it has not been already, to a mold where the final cheese will take shape. The whey of soft cheeses drips through the holes in their molds, pressed out by the cheese’s weight. Other, firmer cheeses are pressed by hand or machine to extract the last bits of whey.

**Ripening.** During the ripening or aging stage, the cheesemaker cares for the cheese at a precise temperature and humidity level until it is ready to eat; this can range anywhere from a few weeks for a soft-ripened cheese to a few years for a wheel of Parmigiano-Reggiano. Depending on the variety, ripening cheeses need to be turned to equally distribute the butterfat and brushed to maintain the rind quality.

### Name-controlled Cheeses

Before the 1951 Stresa Convention in Stresa, Italy, it was impossible for traditional, regional cheesemakers to protect their products from inauthentic forgeries. The delegates to this international conference accomplished two goals: they created a uniform definition of “cheese” to facilitate international trade, and protected by law the names and origins of a select group of treasured traditional cheeses. Protected cheeses fall into two categories. A few cheeses, including France’s Roquefort and Switzerland’s Sbrinz, are given absolute protection—the cheese cannot be made outside of its designated region. A second group of cheeses may be produced in nontraditional areas, but must be clearly labeled with its region of origin. Camembert produced in the United States is a good example of this second group.

“Name-controlled” cheeses must meet stringent laws that go beyond the international standards for processing and safety. The departments and associations that supervise these cheeses differ from country to country (and from cheese to cheese), but generally emphasize the unique, regional quality of the cheese. In Switzerland, for example, cheeses must be native to the area in which they are made. France has the most specific cheese production laws of any country. The Appellation d’Origine Contrôlée (AOC) designation indicates that a cheesemaker has complied with regulations that include the type and breed of animal from which the milk comes, location of production of both milk and cheese, production techniques (including pasteurization), the final composition of the cheese (its fat and moisture content, for example), and the physical and sensory attributes of the cheese, which include its shape, size, and of course, flavor. Spain, Portugal, Italy, and Great Britain are also home to name-controlled cheeses.

The effort to control cheese quality through government standards of identity can be related to similar efforts with wine. Purchasing a French cheese with the AOC designation on the label does not necessarily guarantee quality, however. Subtle differences between individual producers, milk quality, or aging time and conditions can make the difference between a great cheese and a not-so-great one.

### Classifying Cheese

As Pierre Androuët asserts in his fundamental text *Guide du Fromage* (Guide to Cheese), a cheese should simply be what it is—its appearance, aroma, texture, and flavor

Traditional baskets for straining cheese curds. Cyprus, 20th century. Myrtle twigs. The use of myrtle for cheese strainers dates to classical antiquity. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

should be characteristic of the variety to which it belongs. But how does one determinate a cheese's "type"? There are innumerable cheeses, and no single, standardized method for grouping them; rather, authorities employ different classification systems.

General characteristics, such as the type of milk (or whey) used or the country of origin, provide a starting point for discussing broad topics; for example, the relative unpopularity of sheep's milk cheese in the United States compared to European countries, or the social implications of cheese consumption in England as opposed to France. More specific classifications—the moisture content of the cheese (hard, semi-hard, soft, or fresh), whether it was made from pasteurized or unpasteurized milk, or the length of aging—may serve scientific inquiries concerned with bacterial development rates in different cheeses.

When cheese is classified by "type," it is grouped by similar characteristics like taste, smell, and appearance. The rind type and the method of production are often used as determining factors. Steven Jenkins describes eight different cheese "families" (including processed cheese) (*Cheese Primer*, pp. 11–13). These very common categories may help when choosing a cheese at the cheese counter, but a particular cheese may fit into more than one category, or not seem to fit in any.

**Fresh cheese.** After the formation of curds, the cheese (and also, sometimes, the whey) is usually transferred to plastic tubs and covered. The cheeses are eaten fresh, not ripened, and do not have a rind. Cottage cheese, cream cheese, and feta—a pickled cheese—are some common examples of fresh cheeses. Sometimes fresh Mozzarella is also included in this category because it does not form a rind, but this is problematic because Mozzarella curds are heated and stretched.

**Bloomy rind cheeses.** Also called simply "soft ripened cheese," this category includes cheeses like French Camembert and Brie, which are covered with velvety white molds that ripen the cheese from the outside in.

**Washed-rind cheese.** These orange, sticky, stinky cheeses are rubbed with a water, brine, or alcohol solution to invite the growth of ripening bacteria and molds on their rinds. Examples include the French Livarot (nicknamed "The Colonel" because it is ringed with rafia stripes) and Alsatian Munster.

**Natural rind cheese.** These cheeses are self-sufficient, naturally forming their rinds from air contact. Surface-molded goat cheeses and British Stilton are good examples. British farmhouse cheeses are sometimes included in the natural rind category because their permeable cheesecloth wrapping allows them to develop a thick pro-

protective rind. Likewise, Parmigiano-Reggiano and other cheeses are helped to form a rind that still develops largely from air contact.

**Blue-veined cheese.** To allow the growth of their distinctive bluish or greenish interior molds, these cheeses are never pressed. They are typically injected with a mold strain, and then pierced to expose the insides to air. They may be wrapped in foil like Italian Gorgonzola or form natural rinds like British Stilton.

**Uncooked, pressed cheese.** This is a category defined by processing type. These cheeses are pressed to remove whey, but are not cooked (see Treating the Curds).

**Cooked, pressed cheese.** Cheeses such as Swiss Emmental (sometimes Emmentaler) and Gruyère are cooked and pressed in the processes described above.

**Processed cheese.** There is another type of cheese that, because of its overwhelming presence in supermarket refrigerator cases, should not be overlooked. Pasteurized processed cheese is created by heating and mixing a blend of natural cheeses and emulsifiers. These cheeses—American cheese certainly being the best-known in the United States—can retain their flavor and texture qualities in a much broader range of temperature and moisture conditions than can natural cheeses, and for a longer period of time. They are also easy to use in a variety of dishes, and are typically less expensive than natural cheeses. Because the entire product, not just the milk, is pasteurized, and because processed cheeses are often vacuum-packaged, they are uniformly and consistently safe. The nutrient content of processed cheese remains very close to that of natural cheese, although the sodium content may be higher. All of these characteristics make them popular choices not only in the United States but in other countries as well.

Processed cheese food and cheese spread both contain natural cheese and emulsifying agents, but add other ingredients like whey, skim milk, milk powders, or water that raise the moisture content of the product. This causes them to melt or spread more easily. There are also imitation cheese products that contain little or no milk protein. Soy cheese is one example of an imitation cheese product.

### Nutritional Value

The fat content of cheese is noted on its package as a certain percent butterfat. This can be misleading, however, because the fat content is evaluated as a percentage of the solids in the cheese (fat-in-dry-matter), not the overall weight of the cheese. Even a very hard, aged cheese like Parmigiano-Reggiano contains a significant amount of water, about 30 percent. As a cheese ages, it loses moisture, and the fat percentage relative to weight increases, though the fat-in-dry-matter remains the same. Soft cheeses typically have a high fat-in-dry-matter percentage, but they also contain more water than hard cheeses;

their overall fat percentage is much lower, as much as half, the fat-in-dry-matter percentage.

Cheese's greatest nutritional advantage is its high protein content and the digestibility of that protein. In addition, cheese is a valuable source of vitamin A, vitamin B2, and vitamin B12, and the minerals calcium and phosphorus.

People who suffer from lactose intolerance often believe that they must forego cheese altogether. In fact, many cheeses (especially aged, hard cheeses like Parmigiano-Reggiano) contain very little or no lactose, as the lactose is expelled along with the whey. The small amounts of remaining lactose are mostly converted into lactic acid during the aging process.

### Cheese Safety

Cheese has been cited as the vehicle for several bacterial outbreaks—defined as an illness from a common source that affects two or more people. Organisms communicated to humans through cheese have included *Salmonella*, *Listeria monocytogenes*, *Brucella melitensis*, and *Escherichia coli* (including *E. coli* O157). Nearly all of these bacteria are destroyed during the pasteurization process. Raw milk cheeses seem to have been the cause of reported outbreaks more often than pasteurized cheeses. In the interest of public safety, the United States requires that milk for cheesemaking be pasteurized or that the cheese be aged for sixty days. However, recent concerns about the effectiveness of pasteurization, coupled with alarm and confusion over animal disease outbreaks like mad cow disease and hoof-and-mouth disease (which do not affect milk safety) have prompted scientists and government officials to reevaluate the current policy.

A close review of the reported outbreaks reveals that current laws are probably adequate to prevent cheese-borne illnesses, provided that they are strictly enforced and the starting quality of the milk is high. Reports and studies of cheese-borne outbreaks often include “unpasteurized” and “improperly pasteurized” cheese in the same category, implying that milk that has not completed the pasteurization process is of the same quality as raw milk. Traditional cheesemakers would argue that this is not the case. When milk is intended for pasteurization, its initial bacterial quality need not be as high as that of raw milk, as all bacteria will be destroyed in the pasteurization process. However, if the pasteurization process were ever to fail, or if, as some researchers have hypothesized, pasteurization is not effective against all bacteria, milk of low initial bacterial quality increases the risk of cheese-borne illness. Cheesemakers who use raw milk, on the other hand, must take special care to keep it free of dangerous bacteria.

Few outbreaks have been caused by unpasteurized dairy products in which there was not at least one flaw in the production process. Curds from unpasteurized milk have been mislabeled as pasteurized, raw milk

cheeses have been sold before the minimum required aging time, and fresh, unpasteurized Mexican soft cheese has been illegally imported and sold. All of the above cases involved raw milk cheeses, demonstrating the danger that can be associated with that product. Yet, they also show that the existing standards governing raw milk cheese could have prevented the outbreaks, if they had been carefully followed.

Bacterial levels in raw milk will always be higher than in properly pasteurized milk, even when the greatest of care is taken. Aging a cheese for at least sixty days has long been thought to neutralize harmful bacteria, but this may not be true for all types of cheeses and all types of bacteria. Certain groups of people, those with weakened immune systems or special concerns, should not consume raw milk products, particularly soft and semi-soft cheeses. A consumer choosing a raw milk cheese needs to do so fully aware of the possible risks. New labeling requirements could help make sure that people are informed of the risks and the pleasures when they purchase cheese.

**CHEF, THE.** This entry focuses on the emergence of the *chef de cuisine* with the rise of restaurants in the public sphere. Until recently, well-known chefs working in restaurants in Britain and the United States were French or French-trained (for example, Alexis Soyer at the Reform Club in London and Charle Elme Francatelli at Delmonico's in New York City). Japan and China did not have fine dining-style restaurants or the western-style kitchen organization until more recently. African Americans were usually cooks, primarily in domestic settings or as caterers.

The role of "chef" emerged initially from the homes of European nobility, beginning as early as the medieval period. In these grand estates, kitchens were large and populated with numerous workers whose jobs were to help the nobility execute the large, complex banquets important to the maintenance of social position and power during this period. These banquets were about excess, elaborately decorated fish, fowl, and game on platters, dramatic interludes, and massive goblets of wine. As Europe entered the early modern period (1500s and 1600s), the link between social power and social display began to revolve more around exhibits of refinement. Civility and elegance took precedence over excess. The table increasingly became a site for such assertions, hence the kitchen also became more important.

The position of "chef," which comes from *chef de cuisine*, or chief of the kitchen, signifies the highest-ranking worker in a grand hierarchy. Initially he was in charge of running the kitchen, and, like the butler, reported in turn to the head of the household. In twentieth-century parlance, the "chef" traditionally has been a department head. *Chefs de cuisine* were part of the guild system, which regulated artisan practices in France until the French Revolution. Guilds controlled apprentices, the only means available for acquiring training in artisanal crafts and becoming an established craftsman. Guilds also supervised aspects of production. In France up until the nineteenth century, *maître queux*, or master cooks in noble houses, were treated under a separate set of guild statutes. *Cuisiniers* and *traiteurs*, who worked alongside the urban streets, were considered another corporate

Drawing by Franz Freiherr von Lipperheide (1835–1906) showing the type of clothing worn by court cooks during the 1400s. From a hand-colored print published in Berlin in 1884. ROUGHWOOD COLLECTION.

group. Only after the revolution did these two groups meld, eventually leading to the identification of the *chef de cuisine* or head of any large establishment, public or private.

Without question, the most dramatic shift in both identity and practice for the chef was the move from the private to the public sphere as the primary locale for plying the trade. Up until the middle of the eighteenth century, all those with the title *chef de cuisine* worked for the nobility. With increased urbanization, the decline of the monarchical state, and the rise of bourgeois city life, the tables turned on the appropriate sites for asserting social rank. Power shifted to the new domain of the restaurant as fine dining became available to a new social class. *Chefs de cuisine* came to oversee these kitchens. An example is Antoine Beauvilliers, who worked for numerous noble houses but eventually moved to Paris, opened an early fine dining restaurant, La Grande Taverne de Londres, and wrote a cookbook, *L'Art du cuisinier* (1814). The shift from the private to the public sphere took years to complete. Auguste Escoffier, who worked from the 1860s to the 1930s, was the first renowned *chef de cuisine* who trained or worked only in public restaurants.

No evidence exists that women were ever appointed *chefs de cuisine* in any kitchen setting before well into the twentieth century. From the medieval period women worked as domestic cooks throughout Europe, but their roles were clearly defined as servants. In the move from private to public sphere, women were left behind to work in smaller, nonprofessional venues.

*Chefs de cuisine* historically came from France or were trained under French chefs due to the importance of the French court as the seat of “civility” and “culture” for European courtly life, more generally beginning in the early modern period. French haute cuisine symbolized, along with porcelain dishes, ornate silverware, and table decorations, and other French artisanal products, the heights of refinement. Throughout Europe a courtly banquet displaying these items revealed the sophistication and social status of the noble hosts. French chefs were hired to work for the nobility throughout Europe, including the Russian tsar and the king and queen of Britain among others.

French *chefs de cuisine* capitalized on the powerful reputation of French haute cuisine. By the 1600s they began to simultaneously promote and codify their cuisine with the publication of cookbooks, for example Pierre François de La Varenne’s *Le Cuisinier français* (1651), which he dedicated to his noble patron, the Marquis d’Uxelles. Antonin Carême, another *chef de cuisine* who worked in various noble households, created *Le Cuisinier parisien, ou, l’art de la cuisine française au dix-neuvième siècle* (1828), heralded by many as the first cookbook to document the modern approach to French haute cuisine, an approach that focused on refined sauces, extremely elaborate set pieces, and an integrated system of skills and methods. By the late nineteenth century, the ever growing popularity of French chefs both inside and outside of France, the increasingly literate bourgeoisie, and greater possibilities for printing books meant that many chefs, including Urbain Dubois, Georges-Auguste Escoffier, and Jules Gouffe, wrote cookbooks in which they advocated for their mastery of French haute cuisine and its importance in the culinary pantheon. *Chefs de cuisine* managed large kitchens, but they also advocated for a certain culinary sensibility and approach. This approach was disseminated to all the apprentices and cooks working in their kitchens.

Apprenticeship was traditionally the primary means of training cooks. Only after a minimum three-year apprenticeship could a young boy, who generally began his apprenticeship between the ages of ten and thirteen, be called a “cook.” The early years were usually spent cleaning vegetables, scrubbing copper pots, and generally obeying the orders of the cooks, *sauciers*, *poissonniers*, *sous chefs*, and *chefs de cuisine*, all higher up in the hierarchy of kitchen work. After completing an apprenticeship, a young journeyman cook could stay in the establishment where he was trained or search for work elsewhere. The arduous and long journey to becoming a *chef de cuisine*

was not over; years went by before an aspiring cook could hope to become a chef.

Even though the official guild system was abolished after the French Revolution, until the 1870s all culinary training continued to occur within the confines of work establishments. As the culture of work changed in France and in Europe more generally, cooks and chefs began to reconsider this approach. The industrialization of many artisanal production forms on one hand and the increasingly elite status of certain occupations (engineer, pharmacist, doctor) on the other began to concern those involved in the food and beverage trades. Artisanal training was beginning to shift from the workplace to schools supported by the state. The elite alimentary craftspeople, the *chefs de cuisine*, decided the culinary training system needed to change. From 1870 through 1900 a dedicated group of French chefs worked to create a professional culinary school to replace the traditional apprenticeship program. Unfortunately their efforts did not succeed due to much resistance by those in charge of establishments used to the free labor of apprentices and the general belief in the apprenticeship model. Thus in the food trades the link between formal schooling and professional training did not occur until well into the twentieth century. Vocational schools designed to train cooks eventually capable of achieving the status of *chef de cuisine* were founded in Europe and North America by the 1930s and 1940s and throughout the world by the 1960s. However, apprenticeship was the dominant mode of culinary education for entry into professional kitchens through the late twentieth century.

The lineage of the French remained powerful in the organization of work in professional kitchens in the twentieth century. Such dominance is seen in the types of food prepared, the organization of the kitchen, and the identity and training of the head chefs running the kitchen. The imprint of the French on public fine dining meant that the *chef de cuisine* position retained the flavor of that culture.

As the modern restaurant became more a part of the economic culture, however, *chefs de cuisine* were as often found outside the kitchen, promoting their restaurants, dealing with customers, and reading and responding to profit and loss statements. The traditional tasks of overseeing menu and recipe development and supervising the production of food as it goes out of the kitchen into the restaurant remained a vital part of their job descriptions but did not encompass them totally. In larger, more corporate environments, such as hotels, chain restaurants, and college food services, the title *chef de cuisine* was often replaced with “executive chef.” Managing a professional kitchen revolves around a corporate-style identity as much as or more than any cultural or culinary allegiance.

After the 1990s the identity and practice of the *chef de cuisine* began to shift even more, particularly in the

United States and England. Chefs have gone from anonymous blue-collar workers sweating without much acclaim in big, hot kitchens to celebrities with their own cooking shows, product lines, and cookbooks and memoirs. Much like aspiring stars in the movie industry, aspiring cooks go into the profession because they hope to be famous one day. Why has fame come to the once lowly cook and chef? There are many possible answers, but one would have to be the decline of domestic cooking resulting from the increased number of women entering the work force since around 1970. Another answer may be found in the tremendous increase in disposable income for a certain segment of the urban population, which, combined with less cooking at home, has made going to restaurants a combination of high theater and spectator sport. Meanwhile, the expectation that the most powerful and high-ranking people working in public kitchens should be French or at least French-trained began to dissipate. The chef can come from anywhere and creates food that is indebted to but not dominated by French haute cuisine. The *chef de cuisine* has become a citizen of the globe and a respected professional.

**CHICKEN SOUP.** Since prehistoric times, chickens have been mainly kept for their eggs. However, capons and old tough chickens were boiled by a wide variety of groups in Asia, Polynesia, Africa, and Europe. Boiling

permitted the fuller use of chicken parts, such as bones, giblets, feet, neck, and pinions. Consumption of the liquid expanded the quantity of food available, added variety to the diet, and extracted nutritional components that otherwise would have been lost.

Broth was considered a restorative in the ancient world. Chicken broth's special identification with health may have been due to the humoral system of medicine. According to the theory, broth had qualities that eased digestion. As thin foods were believed to be easier to digest, broths were specifically recommended for the sick. Also, the color of chicken soup was similar to the human complexion and was consequently considered nourishing. Whatever the cause of the original belief, it survived into the Middle Ages: Chicken broth was commonly believed to be healthful throughout the Mediterranean and Western Europe. Moslems were particularly taken with chicken broth, as were the Jews. For instance, the classical Persian philosopher and physician Avicenna (980–1037) and the Jewish rabbi, physician, and philosopher Maimonides (1135–1204) regarded chicken soup as beneficial for the ill. This belief survived in Western culinary traditions, particularly those of Jews in Eastern Europe. Jews boiled chickens on Friday. The water in which the chicken was boiled was converted into soup and consumed during the week. Added to the broth were other ingredients, such as carrots, onions, celery, parsnips, kreplach, noodles, and matzoh balls. It was offered to those who were ill as a restorative.

Recipes for using chickens in soups were present in cookery manuscripts and were published in early printed cookbooks, such as Platina's *On Right Pleasure and Good Health* (1470), which contains a recipe that recommends chicken broth for the old and infirm. Chickens were employed in soup-making in England from the earliest days, and soup recipes containing chicken were regularly published as medical prescriptions.

Europeans introduced chickens into the Americas, and chickens were used in soup-making from the sixteenth century onwards. In the United States, recipes for soups containing chicken were published since 1824. However, the actual term "chicken soup" was not commonly used until the late nineteenth century. American manufacturers produced and promoted various commercial chicken soups, the most common of which was chicken noodle soup.

Today, chicken soup is particularly associated with Jewish cookery and is popularly known as the "Jewish penicillin." In 1993 Jack Canfield and Mark Victor Hansen compiled a book titled *Chicken Soup for the Soul*, which built on chicken soup's healthy reputation and set in motion the publications of dozens of "chicken soup" books, including the first cookbooks solely focused on making chicken soup. Some scientific evidence has surfaced to support the belief in the healthful qualities of chicken soup: In addition to protein and vitamins, recent

research has suggested that chicken soup does have a naturally occurring peptide that has positive influence on health.

**CHILD, JULIA.** Possibly more than any other person, from the 1960s onward, Julia Child (1912– ) revolutionized American attitudes toward cooking and eating by embodying two principles: cooks are made, not born, and the pleasure of food comes first. With the supreme confidence of a born clown who grew to six-foot-two, she turned America on to food by entertaining her audience as well as instructing them, making her an icon of the American spirit of energy and good humor. Combining the skills of a highly organized engineer with those of a slapstick comedian, she brought all of America into her home kitchen, through the doubled media of books and television, to wish them "*bon appétit*."

Born Julia McWilliams in Pasadena, California, to a family who had their own cook, Child did not set foot in a kitchen until she married at thirty-four. A graduate of

"If I can make a soufflé rise, so can you."

—Julia Child, in *The New Yorker*, 13 October 1997, p. 91

"No matter what happens in the kitchen, never apologize."

—Julia Child, in Fitch, *Appetite for Life*, p. 142

"It's a shame to be caught up in something that doesn't absolutely make you tremble with joy!"

—Julia Child, in Fitch, *Appetite for Life*, p. 480

Julia Child has become an icon of modern American cooking. She is shown here holding a bowl of tomatoes. COURTESY OF AP/WIDE WORLD PHOTOS.

Smith College and a veteran of World War II, she wed a fellow member of the Office of Strategic Services (OSS) whom she had met in Ceylon, Paul Child, who loved art, good living, and good food. When her husband was assigned to the Paris office of the United States Information Service in 1948, Child quickly enrolled in the *Cordon Bleu* school of cooking. There she joined with Louise Bertholle and Simone Beck to found *l'École des Trois Gourmandes* (the school of the three gourmets). The first volume of *Mastering the Art of French Cooking* appeared in 1961. The second volume, coauthored by Child and Beck, followed in 1970. Together, the encyclopedic volumes introduced “the servantless American cook” to the classic techniques and terminology of French bourgeois cooking translated into American terms and American kitchens.

While the success of the first volume was phenomenal, it was but a prelude to Child’s success as a television performer in 1962, in which her infectious enthusiasm and natural clowning were simultaneously embraced and parodied. She followed *The French Chef* series for Boston’s public station WGBH, from 1963 to 1973, by eight more series over the next decades, where she often served as interlocutor to guest chefs. Usually a series such as *In Julia’s Kitchen with Master Chefs* was followed by a book of similar title, so that her publishing output was as prolific

as her broadcasting. To date she has published eleven volumes.

Like James Beard, Child linked America’s East to West, with houses in both Cambridge, Massachusetts, and Santa Barbara, California. She was among the first to establish an American food community with a national educative mission and proselytized universities to recognize gastronomic studies as part of a liberal arts curriculum. With California winemakers Robert Mondavi and Richard Graff, she founded the American Institute of Wine and Food in 1981 and helped transform the International Association of Cooking Professionals (IACP) into a comprehensive trade organization.

Her personal generosity and breadth of spirit brought amateurs together with professionals and made her a goodwill ambassador, not just between America and France, where the Childs built a house in Provence, but also internationally. She has fulfilled in her own life her admonition in her first book to “above all, have a good time.” By taking what she called the “lah-de-dah” out of French cooking, she has made the pleasures of food available to ordinary Americans everywhere.

**CHILI PEPPERS.** Chili peppers (genus *Capsicum*) can be eaten fresh or dried, raw or cooked, alone or mixed with other foods. They add zest to any food—meat, poultry, seafood, starch, vegetable, fruit—whether eaten by themselves or as an ingredient in a prepared dish. Peppers are the most popular spice and condiment in the world. They are consumed daily by one-quarter of the world’s population, and the rate of consumption is growing. Nonpungent or sweet peppers are also consumed as a vegetable, but are the less popular spice. All capsicums were pungent before being domesticated by prehistoric New World peoples and before the breeding of nonpungent (sweet) types. Peppers, both pungent and nonpungent, are the fruit of perennial shrubs that were unknown outside the tropical and subtropical regions of the Western Hemisphere before 1493, when Christopher Columbus returned from the first of his voyages in search of a western route to the East Indies. Although he did not reach those exotic spice lands as he had proposed, his return to Spain with examples of a new pungent spice

discovered during his first voyage to the eastern coast of the Caribbean island of Española (Dominican Republic and Republic of Haiti) is well documented in his journal. Today capsicums are not only consumed as a spice, condiment, and vegetable; they also have many other uses—as coloring agents, in landscape design, as ornamental objects, in decorative design—and have great potential in the field of medicine.

### Nutrition

Nutritionally, capsicums are a superior food. They are an excellent source of the B vitamins, are superior to citrus as a source of vitamin C when eaten raw, and they contain more vitamin A than any other food plant by weight. Vitamin A increases as the fruit matures and dries but is not affected by exposure to oxygen, while the production of vitamin C in peppers diminishes with maturity and drying and is, as in all plant foods, destroyed by exposure to oxygen. Capsicums also contain significant amounts of magnesium, iron, thiamine, riboflavin, and niacin. Even though chili peppers are not usually eaten in large quantities, small amounts are important where traditional diets provide only marginal amounts of vitamins. However, ripe nonpungent varieties, such as bell peppers, can be eaten as painlessly as an apple while providing more food value.

### Capsaicin: The Pungent Principle

A unique group of mouth-warming, amide-type alkaloids containing a small vanilloid structural component known as capsaicin act directly on the pain receptors of the mouth and throat to produce the burning sensation as-

sociated with peppers. This vanilloid element is also present in pungent spices such as ginger and black pepper. Birds and a few other creatures such as snails or frogs do not have neuroreceptors for pungent vanilloid compounds and thus capsaicin does not cause them pain.

V. S. Govindarajan (1985) has suggested “pungency” as the proper term for the perception of the hot or burning sensation humans have in response to such foods rather than to others. Consequently, the response to chili peppers should be defined as pungent rather than hot, stinging, irritating, sharp, caustic, acrid, biting, burning, and spicy. He also suggests that pungency be given the status of a gustatory characteristic of food, as are sweet, sour, bitter, saline, astringent, or alkaline.

The vanillyl amide compounds or capsaicinoids in *Capsicum* are predominantly capsaicin (C 69 percent), dihydrocapsaicin (DHC 22 percent), nordihydrocapsaicin (NDHC 7 percent), homocapsaicin (HC 1 percent), and homodihydrocapsaicin (HDHC 1 percent). Several more analogues of these in trace amounts bring the number to ten (Masada et al., 1971; Treace and Evans, 1983). The primary heat contributors are C and DHC, but the delayed action of HDHC is the most irritating and difficult to quell. These compounds form a pungent group, of which capsaicin is the most important. Two of these five capsaicinoids cause the sensation of “rapid bite” at the back of the palate and the throat, while the others cause a long, low-intensity bite on the tongue and midpalate.

Most of the organs secreting these pungent alkaloids are localized in the fruit’s placenta, to which the seeds are attached, along with the dissepiment (veins or crosswalls). The seeds contain only a low concentration

## CHILI, CHILLI, CHILE, OR PIMENTO?

Columbus believed that he had arrived in the Orient when he landed on the islands of the Caribbean Sea. He was so convinced of this that he called the islands the Indies, the natives were labeled Indians, and to the confusion of all who came after him, the pungent spice they ate was named *pimiento* after the completely unrelated black pepper—*pimienta*—that he sought. The indigenous Arawaks, his Indians, called the fruit *axí* (pronounced “aah hee”) that was transliterated in Spanish to *ají* (*ajé* or *agí*).

Today the pungent varieties are still called *ají* in the Dominican Republic (formerly Española) and a few other places in the Caribbean and much of South America. In the Andean area the ancient words *uchu* and *huayca* are used for capsicums by some Amerindian groups. In Spain American peppers are called *pimiento* or *pimientón* (depending on the size) after *pimienta* or black pepper from India. However, the Spanish names did not stay with the plant through Europe; it is called *peperone* in Italy, *piment* in France, and *paprika* by the Slavic peoples in the Balkans.

In 1519 when the Spaniards arrived in Mexico, the Nahuatl-speaking natives called their fiery fruit *chilli*. The main interest of the initial Iberian explorers was conquest, then gold and silver; chilies and other plants were of little concern to them. Fifty years later a different type of Spaniard arrived. Dr. Francisco Hernandez, physician to the King of Spain, was the first European to collect plants in the Americas. Hernandez lived in Mexico from 1570 to 1577, and when he returned to Spain, he produced four books on the natural history of the plants and animals he had found in New Spain. He heard the Nahuatl speakers pronouncing the name of their pungent native spice “chee yee.” Consequently, when he wrote about that plant, he gave the Nahuatl word a Spanish spelling, using the double *ll* to reproduce the “y” sound he had heard the natives make. The Nahuatl stem *chil-* refers to the chili plant. It also means ‘red.’ To the generic word “chilli” the term that described the particular chili cultivar was added (e.g., *tonalchilli* for a chili of the sun or summer, *chiltecpin* for a flea chili, etc.). At some point the Spanish speakers in Mexico changed the original Hernandez spelling to *chile*. Today, that word refers to both pungent and sweet types of chilies and is used Nahuatl-style combined with a descriptive adjective, such as *chile*

*colorado* (for a red chili) or *chile poblano* (for a Pueblo chili). Confusingly, the same Mexican variety can have different names in different geographic regions, in various stages of maturity, or in the dried state.

In Portuguese *pimenta* is used for capsicums and qualifies the various types—*pimenta-da-caiena*, cayenne pepper; *pimenta-da-malagueta*, red pepper; *pimenta-do-reino*, black pepper; *pimenta-da-jamaica*, allspice; while *pimentão* is pimento, red pepper, or just pepper. *Ají* and *chile* are not found in a Portuguese dictionary, nor did Portuguese settlers or explorers carry these words with them in their travels.

The Dutch and English were probably responsible for introducing the current capsicum names to the eastern part of the Old World because in Australia, India, Indonesia, and Southeast Asia in general, *chilli* (spelled *chillies* or sometimes *chilly*) is used by English speakers for the pungent types, while the mild ones are called capsicums. Each Far Eastern language has its own word for chilies—*prik* in Thai and *mirch* in Hindi, to name but two.

The most confusion with regard to spelling exists in the United States, especially in California and the Southwest. Here, one finds both the anglicized spelling *chili* (*chilies*) and the Spanish spelling *chile* (*chiles*) used by some for the pungent fruits of the *Capsicum* plant, while “chili” is also used as a short form of *chili con carne*, a variously concocted mixture of meat and chilies. *The Oxford English Dictionary* offers *chilli* as the primary spelling, calling *chile* and *chili* variants. *Webster’s New International Dictionary* prefers *chili*, followed by the Spanish *chile* and the Nahuatl *chilli*. *Chilli* remains the spelling most used by English-speaking people throughout the world.

For the sake of clarity and consistency, it would help if capsicums or peppers were used when speaking of the fruit of the *Capsicum* in general, both sweet and pungent; chilli or chilli pepper for the pungent types; chili for the spicy meat dish; and pimento for the sweet, thick-fleshed, heart-shaped red capsicum. *Chile* (in italics) should refer to a native Mexican cultivar or, in its not italicized form, it should refer to the long green or red variety from New Mexico or California. Whenever possible, the name of the specific fruit type, group, or cultivar name should be used.

of capsaicin resulting from this contact. The amount of capsaicin in a pepper is influenced by the growing conditions of the plant and the age of the fruit and is pos-

sibly variety-specific. The amount of capsaicin will increase under dry, stressful conditions. About the eleventh day after the fruit sets, the capsaicin content

begins to increase, becoming detectable when the fruit is about four weeks old and peaking just before maturity, then dropping somewhat as it ripens (Govindarajan, 1985). Sun-drying generally reduces the capsaicin content, but when the fruits are air-dried with minimum exposure to sunlight, the highest retention occurs.

Capsaicin has virtually no odor or flavor, making it hard to detect by chemical tests, but a drop of a solution containing one part in 100,000 causes a persistent burning on the tongue. Although capsaicin is eight times more pungent than the piperine in black pepper, it only obstructs the perception of sour and bitter; it does not impair the discernment of other gustatory characteristics of food, as does black pepper. Eating capsaicin also causes gustatory sweating. The neck, face, and front of the chest sweat as a reflexive response to the burning in the mouth. Capsaicin activates the digestive systems by acting as an irritant to the oral and gastrointestinal membranes. That is a desirable irritation because it increases the flow of saliva and gastric acids. Very little capsaicin is absorbed as it passes through the digestive tract, an uncomfortable consequence of which is “jaloproctitis,” or burning defecation.

Ingesting capsaicin by eating chilies not only increases the flow of saliva and gastric secretions but also stimulates the appetite. These functions work together to aid the digestion of food. The increased saliva helps ease the passage of food through the mouth to the stomach where it is mixed with the activated gastric juice. These functions play an important role in the lives of people whose daily diet is principally starch-based (Solanke, 1973).

Although capsaicin is not water-soluble, the addition of a small amount of chlorine or ammonia will ionize the capsaicin compound, changing it into a soluble salt. The same solution can be used to rinse capsaicin from the skin. When handling more than one or two chili pods, one should wear rubber or plastic gloves and/or keep a bowl of water with chlorine handy so that hands and skin can be rinsed immediately. Capsaicin can be quite painful if it comes into contact with the eyes, nose, or any other orifice. Capsaicin is soluble in alcohol, as are many organic compounds. Oral burning can be relieved by lipoproteins such as the casein found in milk and yogurt. The capsaicin is removed by casein in a manner similar to the action of a detergent, thereby breaking the bond it had formed with the pain receptors in the mouth (Henken, 1991). It is the casein, not the fat found in milk products, which relieves the burning; therefore, butter and cheese do not have the same effect as milk and yogurt.

Studies of the relationship of capsaicin to substance P, a neuropeptide that sends the message of pain to the brain, suggest that capsaicin can deplete nerves of their supply of substance P, thereby preventing the transmission of these pain signals (Rozin, 1990). Thus, capsiacin

is being used to treat the pain associated with shingles, rheumatoid arthritis, and phantom-limb pain. Importantly, capsaicin may prove to be a non-habit-forming alternative to the addictive drugs used to control pain. It does not act on other sensory receptors such as those for taste and smell, but is specific to pain receptors. Medical researchers are finding this specificity to be a valuable aid in their studies.

### Aroma, Flavor, and Color

The carotenoid pigments responsible for the color in capsicums make peppers commercially important worldwide as natural dyes in food and drug products. Red capsanthin is the most important pigment. All capsicums will change color as they mature from green to other hues—red, brown, yellow, orange, purple, and ripe green.

The flavor compound of capsicums is located in the outer wall (pericarp): very little flavor is found in the placenta and crosswall, and essentially none in the seeds. Color and flavor go hand in hand because the flavoring principle appears to be associated with the carotenoid pigment: strong color and strong flavor are linked. Two Latin American species, *Capsicum pubescens* (rocoto) and *C. chinense* (habanero), are more aromatic and have a

One of the first European depictions of peppers appeared in Leonhard Fuchs's *New Kreüterbuch* [New Herbal] published at Basel, Switzerland, in 1543. This plate from Fuchs shows the pepper now commonly known as Cayenne. ROUGHWOOD COLLECTION.

decidedly different flavor than those of the more commonly consumed *C. annuum* var. *annuum*.

Smell and taste are separate perceptions. Several aroma compounds produce the fragrance. The taste buds on the tongue can discern certain flavors at dilutions up to one part in two million, but odors can be detected at a dilution of one part in one billion. The more delicate flavors of foods are recognized as aromas in the nasal cavity adjacent to the mouth. Sensory cells with this function are much more discerning than the tongue.

### Origin

It is difficult to determine where *Capsicum* originated because the genus is still not fully understood (Eshbaugh, 1980, 1993). If the genus is defined as limited to tax-producing pungent capsaicin, the center of diversity occurs in an area from present-day Bolivia to southwestern Brazil. However, if it is redescribed to include other non-pungent taxa, a second center of diversity would center

in Mesoamerica (Eshbaugh, 1993). It is certain, nevertheless, that the first ancestor of all domesticates originated in South America.

There are indications that the better-known *Capsicum annuum* originally was domesticated in Mesoamerica, and the next best well-known, *C. chinense*, originated in tropical northern Amazonia. The two less familiar species, *Capsicum pubescens* and *C. baccatum*, are more commonplace in the Andean and central regions of South America. The first two species were introduced to the Europeans after Columbus's voyages to the New World, while the other two species were not encountered until later, only recently becoming known outside their South American homeland.

The tropical perennial capsicum spread rapidly around the Old World tropics after 1492. Chili pepper has since become the dominant spice and condiment in the tropical and subtropical areas known as the "pepper belt," and in temperate regions sweet peppers are an important green vegetable and are grown as an annual. Concentrated breeding studies have produced *Capsicum* varieties that can be cultivated in environments quite different from their original tropical home and modern forms of transportation have made peppers of all fruit types available worldwide.

### History

In his journal Columbus faithfully recorded his sighting of a new pungent, red-fruited plant that he called pepper, and he brought back specimens to Spain, marking the beginning of the history of capsicums for the people of the Old World (Anghiera, 1964; Morison, 1963). However, the pungent fruits were not originally discovered by Columbus. When nonagricultural Mongoloid peoples from northeastern Asia, who had begun migrating across the Bering Strait during the last Ice Age, reached the subtropical and tropical zones of their new homeland in the Western Hemisphere, they found capsicums widespread, having been carried by their natural dispersal agents, principally birds, from their nuclear area in southeastern Bolivia or southwestern Brazil to other regions (Pickersgill, 1984). Prehistoric plant remains and depictions of chilies on artifacts provide archaeological evidence of the use and probable cultivation of wild capsicums as early as 5000 B.C.E. It has also been shown that native Americans had domesticated (genetically altered) at least four species by the time of Columbus's discovery (Heiser, 1976; MacNeish, 1967). No other species have been domesticated since that time.

When Columbus arrived in the West Indies, he found at least two species of capsicums being cultivated by the Arawaks, agriculturists who had migrated north from their homeland in northeastern South America to the Caribbean Islands during a twelve-hundred-year period beginning about 1000 B.C.E. (Anghiera, 1964; Watts, 1987). Those migrants had traveled by way of pre-

## PLANTING PEPPERS

Pepper seed should not be planted directly into the soil outdoors; they are best transplanted. Start the seed in a greenhouse, in flats, or in hotbeds at least six weeks before the first frost-free date. Sow them as thinly as possible on a sterile medium and cover no deeper than the thickness of the seed. Water carefully from the top so as not to dislodge the seed. From the time of sowing until transplanting and well started, never permit the seed or seedlings to dry or wilt. Germination will require twelve to twenty-one days at a constant temperature of 70°F (21°C) for *Capsicum annuum* var. *annuum*, but longer for the other species. When four or more true leaves are well formed, transplant the seedlings into containers or flats containing equal parts peat, sand, and loam. Grow them at 70°F (21°C). After the plants attain a height of 12 to 15 centimeters and all danger of frost is past, transplant them deeply in friable soil that is not below 55°F (13°C). Space the plants 12 inches apart in rows 15 inches apart. Add a cup of water to each transplant and cover with a hot cap; irrigate immediately. Full sun and a well-drained soil are necessities. Peppers are a warm-season crop that grows better in a moderate climate, one that is not so cold as to cause freezing or too hot to set fruit. If night temperatures rise above 80°F (27°C), the plant will not bloom. The optimum temperature for good yield is between 65°F (18.5°C) and 80°F (26.5°C) during fruit setting (Andrews, 1993).

sent-day Trinidad and the lesser Antilles, bringing with them a tropical capsicum that had been domesticated in their homeland. They also brought the word “*aji*”—by which the plant was, and still is, known in the West Indies and throughout its native South American habitat (Heiser, 1969). Later a second species that had been domesticated in Mesoamerica probably came over different trade routes to the West Indies along with other Mesoamerican food plants—maize, beans, and squash (Sauer, 1966). However, *chilli*, the native Nahuatl name for the endemic Mesoamerican pepper plant, did not travel with it. It was that later arrival, a more climatically adaptable pepper than its earlier South American relative, which was introduced by Columbus to the Old World (Andrews 1993, 2000).

The new American plants from the tropical West Indies were not suited to the climate and day length of the Iberian Peninsula and other parts of Europe and the Mediterranean. Twenty-nine years later the conquest of Mexico, followed by that of Peru, revealed plants that were more climatically suitable to cultivation in temperate Europe and the Middle East. Within fifty years of the first arrival of capsicum peppers on the Iberian Peninsula and on islands such as Cape Verde, the Canaries, Madeira, and the Azores, American chili peppers were being grown on African coasts and in India, monsoon Asia, southwestern China, the Middle East, the Balkans, central Europe, and Italy. In 1542 Leonhart Fuchs, a German, was the first to describe and illustrate several types of peppers, which at the time were considered to be natives of India. It was not the Spaniards but the Portuguese who were responsible for the early diffusion of New World food plants to Africa, India, and the Far East, abetted by local shipping and traders following long-used trade routes. These mariners and merchants enabled the spread of the new American plants throughout the Old World with great rapidity (Boxer, 1969a).

### The Route from the New World

The dispersal of capsicum is not as well documented as that of plants such as maize (corn), tobacco, sweet potatoes, manioc (cassava), beans, and tomatoes. However, it is highly probably that capsicums followed the same trade route as the “three sisters”—corn, beans, and squash. The four plants have been closely associated throughout history.

In 1494 the pope’s Treaty of Tordesillas divided the world on a line extending around the globe at a point 370 leagues west of the Cape Verde Islands. The Spanish were granted everything discovered west of the line and the Portuguese everything to the east of it. This arrangement persisted until the Dutch, followed by other European nations, challenged this monopoly at the end of the sixteenth century. Although the Portuguese were not active in the Spanish Caribbean until after 1509, when they brought the first slaves from Africa, they had acquired American maize by some yet unexplained means—per-

haps in Galicia, Madeira, or the Canaries—before 1500, and were growing it on the west coast of Africa from where it was introduced to the Cape Verde Islands in 1502 (Jefferys, 1975). From early Portuguese “factories” in Africa and/or the eastern Atlantic Islands, the American food plants went to the east coast of Africa and India on the annual voyages of the *Nao da Goa* and other trading ships traveling between Lisbon and Goa on the Malabar Coast of western India (Boxer, 1984). As evidence of their coming from that African area, they were called “ginnie” (Guinea) peppers.

The natives of Africa and India, who were long-accustomed to pungent seasonings such as the African melegueta pepper (*Aframomum melegueta*), a member of the ginger tribe, Indian black pepper (*Piper nigrum*), and ginger (*Zingiber officinale*), readily accepted the fiery new spice. The Old World tropics provided an acceptable climate for the New World spice. The plants produced by the abundant, easily stored seed were much easier to

There are thousands of varieties of peppers. Shown here are several heirloom specimens, including Bull's Nose, Yellow Cayenne, and Chile Azul de Guinea. PHOTO BY L. WILBUR ZIMMERMAN. ROUGHWOOD SEED COLLECTION.

cultivate than native spices, making capsicums an inexpensive addition to the daily diet. Along the Malabar Coast of India, three varieties of capsicums were being grown and exported within fifty years of Columbus's discovery of the New World (Purseglove, 1963).

Once established in India, chili pepper became part of spice shipments from the Far East along the new Portuguese route around Africa to Europe, over the ancient trade routes to Europe via the Middle East, and also on existing routes to monsoon Asia (Lobelius, 1576). The Portuguese also brought chilies to Southeast Asia and Japan. Once established in these areas, birds carried pepper seed from island to island and to humanly inaccessible inland areas.

In southwestern China, American foods were known by the middle of that century, having been transported over the ancient caravan routes from the Ganges River across Burma and across western China into India and the Middle East (Ho, 1995). This is evidenced by the fact that today the cuisines of southwestern Szechuan and Hunan use more chili peppers than any other area in China.

After the Spanish conquest of the West Indies, Mexico, Mesoamerica, and Peru, trade with the new colonies was very limited (Braudel, 1976). Once Mexico was subjugated and opened for colonization, the Spaniards virtually deserted the West Indies for the North American continent, leaving the islands inhabited primarily by African slaves brought there by the Portuguese. By that time, the indigenous peoples of those islands were es-

entially extinct. For the first fifty years following the New World's discovery, the Spanish rulers were more interested in problems within the Habsburg Empire than in their new acquisitions and, as a consequence, Spanish trade with the New World came to a standstill (Watts, 1987). During this period Portuguese and other European opportunists entered the Caribbean and established trading footholds.

In 1492, after ousting the Moors from Spain following their seven-hundred-year occupation, the Spaniards established dominance over the western Mediterranean while the Ottoman Turks succeeded in seizing control of northern Africa, Egypt, Arabia, the Balkans, the Middle East, and the eastern Mediterranean Sea. At that time, for all practical purposes, the Mediterranean was two separate trading spheres divided by Italy, Malta, and Sicily with little or no trade or contact between the western Mediterranean and the Ottoman Empire (Braudel, 1976). This is an important consideration in the history of the diffusion of American peppers and other economic plants.

Venice was the center of the spice and oriental trade for central Europe, and Venetian merchants depended on the Ottoman Turks to supply them with goods from the Asia. The Muslim Arab and Gujurati traders received supplies from Portuguese ports on the west coast of India and Hormuz at the mouth of the Persian Gulf. Goods introduced to central Europe were taken to Antwerp and from there to the rest of Europe. Antwerp, the major European shipping port, also received goods from the Far

East, and from the Portuguese sources via India, Africa, and Lisbon. From these trading routes chili peppers came to be known in Italy by 1535 (Fernández de Oviedo, 1535), Germany by 1542 (Fuchs, 1543), England before 1538 (Turner, 1965), the Balkans before 1569 (Halasz, 1963), and in Moravia by 1585 (L'escluse, 1611). It was only in the Balkans and Turkey that chili peppers were used to any extent until the Napoleonic blockade cut off the supply of spices to Western Europe. Without their usual supply of spices, Europeans turned to Balkan paprika (chili pepper) as a substitute.

Most Europeans had grown capsicums only as ornamentals and believed that peppers were native to India and the Far East until the mid-nineteenth century when botanist Alphonse de Candolle produced convincing linguistic evidence for the American origin of the genus *Capsicum* (Candolle, 1852).

It was only after capsicums had become established in Asia, the Middle East, and Europe that the Spaniards played any part in the movement of New World plants to places other than Spain, Italy, and perhaps Western Europe. The Pacific Ocean route of the Spanish Manila-Acapulco galleon was established in 1565 and operated for 250 years (Schurz, 1939). This ship was a major means for transferring plants as well as trade goods between Mexico and the Far East. At approximately the same time the Spanish colonies of Saint Augustine, Florida, and Santa Fe, New Mexico, were founded. Those first European settlements in the present-day United States initiated Caribbean and Mexican trade with Florida and the Southwest, respectively, forty years before other northern Europeans began colonizing the east coast of North America. The first peppers to enter an English colony were sent to Virginia in 1621 by the governor of the Bermuda Islands.

### Condiment, Spice, and Vegetable

At the time of World War II, one-fourth of the world's population, primarily in the pantropical belt and Korea, ate capsicums daily. Since that time the consumption of peppers as a spice, condiment, and vegetable has grown annually and is no longer limited to the tropical and subtropical areas. Some of the more common food products made with chilies are curry powder, cayenne pepper, crushed red pepper, dried whole peppers, chili powder, paprika, pepper sauce, pickled and processed peppers, pimento, and *salsa picante*. In 1992 *salsa picante*, a bottled sauce of Mexican origin made with a base of chilies, onions, and tomatoes, overtook tomato catsup as the top selling condiment in the United States.

Throughout the world capsicums are used as a source of color/pigment not only for commercial products such as cheese, sausage, salad dressings, and meat products, but also for drugs and cosmetics. Dried red peppers are added to hen feed to ensure yellow egg yolks and in caged bird feed to enhance the natural color of plumage.

The use of capsicums goes beyond that of a comestible. The florist and landscape industries have found their ornamental qualities to be of considerable value. The multihued, variform fruits of the attractive podded plant have become popular decorative motifs, not only in the Southwest but throughout the country. They can be found on chinaware, glasses, fabrics, in flower arrangements, as Christmas tree lights and ornaments, on men's neckties, even as hummingbird feeders, to name but a few.

### Ritual, Folklore, and Magic Uses

The medical profession has discovered that certain folk medical practices employing chilies, many of which are prehistoric in origin, have merit and are being used by modern physicians to treat arthritis, shingles, toothache, and other types of pain. Research in this area continues. Solanaceous plants, which include capsicums, potatoes, datura, belladonna, tobacco, and tomatoes, have long been used in charms, rituals, magic, ceremonies, divination, therapeutical practices, and other customs. Pre-Columbian Indian medicine men used peppers mixed with other substances for such ailments as coughs, poor digestion, ear infection, sore throat, injuries to the tongue, and to expedite childbirth.

The shape of most chili pepper pods, and their pungency/heat and redness have led them to be associated with male sexuality. In some cultures, eating chili peppers is thought to arouse passions, while in others people abstain from eating them in particular places or under certain conditions. Ancients used them in warfare and as torture or punishment and, even today, they are used as a repellent to ward off human or animal aggressors.

### Diagnostic Descriptions

The Solanaceae, which includes such plants as potatoes, tomatoes, eggplant, petunias, and tobacco, is the family of which the genus *Capsicum* is a member. Currently, the genus consists of at least twenty-five species, four of which have been domesticated, and two others are cultivated extensively. The flowers, not the fruits, are the definitive feature of the genus. Although many of these are consumed by humans, it is those six species belonging to three separate genetic lineages that are of concern to human nutrition:

- *Capsicum pubescens* (first mentioned by Ruiz and Pavon, 1797). This domesticated species is the most distinctive in the genus. The flowers have comparatively large purple corollas (sometimes white infused with purple), which are solitary and erect at each node. The wavy, dark brownish-black seeds in the fruit, and those blossoms are unique among the capsicums. This extremely pungent chili, called *rocoto*, was domesticated in the Andean region of South America and is yet virtually unknown in other parts of the world. Its cultural requirements are cool, free-growing conditions and a long growing season.

## SELECTION, PREPARATION, AND SERVING

Capsicums are a fruit that is used like a vegetable. Any type of pepper can be gathered when it is green, but when fully mature it is red, orange, yellow, purple, or brown. The two compounds that produce the pungency and flavor do not develop immediately, but increase gradually with maturity. As a consequence, immature fruits are less pungent and less flavorful than mature ones. A *chipotle*, or fully dried ripe red jalapeño is much more pungent than the green jalapeño, and a mature red bell pepper is much sweeter and flavorful than a green one. Until recently, the consumer had to settle for green rather than ripe fruit because the latter did not ship or store well. Better, faster shipping and storage facilities are changing that so that one may savor the flavor of a fully ripe pepper. Except for green bell peppers, capsicums are a seasonal crop, and the best selection will be available in the summer and fall. The most desirable fruits are those with glossy, smooth skin that is firm to the touch.

Peppers are best stored in the refrigerator. They may be kept there for weeks only if the fresh pods are dried with a clean cloth, and placed in an airtight container or a tightly sealed heavy zip-lock plastic bag. It is important to remove as much of the oxygen as possible before placing the tightly closed container in the refrigerator. Each time the container is opened, the unused pods must be dried and air removed before resealing. Once a week the peppers should be removed from the refrigerator and allowed to return to room temperature, then wiped dry, returned to the container, and sealed. If they cannot be stored this way, it is best to freeze them and then use them for cooking. If they are to be kept out of the refrigerator or if there is no time to withdraw the air, they should be placed in a paper container. If they are put in an air-filled plastic bag, they will rapidly spoil.

Dried peppers will keep almost indefinitely if properly stored. They should be kept in tightly closed jars or heavy plastic bags in a dry, cool place, preferably the refrigerator or freezer. Freezing the dried peppers before storing will kill any insect larvae and eggs. The peppers should be monitored for insects or mildew.

Before peppers are used in a favorite recipe, they must be washed, stemmed, veined, and seeded. Some cooks prefer to remove the skin but this is only necessary when using tough skinned *poblanos* or the New

Mexican chile and any of its varieties. The large bell types, ethnic peppers (*Cubanelle*, Italian), pimentos, and others of these types should be parboiled or blanched for 2 to 3 minutes before being used whole for stuffing or filling, if the filling is not to be cooked in the pepper shell. Remove them from the heat immediately and plunge them into iced water to stop the cooking process. Small chilies need only to be washed, stemmed, seeded, and veined without skinning. Usually, if a recipe calls for a pepper to be roasted or blistered, it is not only to remove the skin, but also because the charred flavor is desirable.

Frozen peppers can be used for seasoning and cooking or as stuffed peppers; they are too soft for salads. If the skins are left on before freezing, most of the nutritive values is retained. When freezing pungent chilies, par-boiling before freezing will prevent capsaicin loss. Dry small chilies and spread on a pan before freezing. When frozen hard, remove from the pan and immediately place them in a dry plastic bag. Return to freezer. Open bag and pick out a few as needed, being careful to prevent the thawing of those remaining in the bag. Return to freezer.

Peppers can be sun-dried, oven-dried, smoked, or dehydrated, but none of these methods are very practical for the modern home cook who is pressed for time. Sun-drying is an ancient method best adapted to arid climates, but is not feasible in humid areas. It takes several days in a dry, sunny locale. Oven-drying is a tedious process requiring the peppers to remain in a 140°F oven for up to 24 hours. Smoking is another method of artificially drying peppers that is seldom used in the United States. It is the procedure by which jalapeños are slowly dried and imparted with a smoky flavor to become *chipotles*. Dehydration is drying with heat from a man-made source. This process is not only faster, but also produces a much better product than the other methods.

The dried product can be placed in a processor or blender and flaked or powdered. The ground product will keep better once refrigerated. Whole pods may be used in recipes that require a long cooking time and a large amount of water such as those for soups or stews.

Many widely available and popular cookbooks provide directions and recipes for preparing and serving capsicums.

There are no sweet varieties. The fruit deteriorates rapidly because of its fleshy nature; consequently, it does not store or travel well. The best-known cultivars are *rocoto*, *locoto*, *manzana*, and *chile caballo*.

- *Capsicum baccatum* var. *pendulum* (mentioned in the work of Willdenow, 1808; Eshbaugh, 1968). It has an easily recognized flower with a cream-colored corolla marked with greenish-gold blotches near the

base of each petal and anthers that are whitish yellow to brownish and is solitary at each node. An elongate fruit with cream-colored seeds is most typical. It is indigenous to the lowlands and mid-elevations of Bolivia and neighboring areas. In much of South America, where all pungent peppers are called *ají*, *C. baccatum* is the “Andean *ají*” (Ruskin, 1989). Little known beyond South America until now, it is being discovered by pepper fans. Only this species and the common annual pepper have nonpungent cultivars. The best-known cultivars are Andean *ají*, *cusqueno*, *puca-uchu*, *ají limon*, and *datil*.

- *Capsicum annuum* var. *annuum* (first mentioned by Linnaeus, 1753). The flowers with white corollas and purple anthers are solitary at each node (occasionally two or more). The variform fruit usually has firm flesh and straw-colored seeds. A multitude of pungent and nonpungent cultivars of this Mesoamerican domesticate now dominate the worldwide commercial pepper market. A relationship between *C. annuum*, *C. chinense*, and *C. frutescens* has caused the three to be known as the *C. annuum* complex. This relationship creates a taxonomic predicament. Some authors still recognize the first two as distinct but tend to have difficulty determining where *C. frutescens* fits into the picture, if indeed it is a separate species. The best-known cultivars are bell, cayenne, jalapeño, serrano, pimiento, *poblano*, New Mexican chile/Anaheim, and cherry.
- *Capsicum annum* var. *glabrisculum* (mentioned in the work of Dunal, 1852; Heiser and Pickersgill, 1975). It is a semiwild species known as bird pepper. Its distinct flavor and high pungency cause it to be avidly consumed throughout its natural range, which extends through the southernmost parts of the United States to Colombia. This highly variable, tiny, erect, usually red pepper is cultivated commercially in the area around Sonora, Mexico, and seems to be in the process of domestication. Birds also consume it avidly. These chilies, which have many vernacular names and almost as many synonyms (*C. aviculare* is the most common), sell for ten times the rate of cultivated green bell peppers. The best-known cultivars are *chiltepin*, *chilpequin*, *malaqueta*, and bird pepper.
- *Capsicum chinense* (first mentioned by Jacquin, 1776). Its flowers are always two or more small, white to greenish white corollas with purple anthers hanging at each node, often in clusters. The variform fruit has cream-colored seeds that tend to require a longer germination period than *C. annuum*. Its domestication occurred in the lowland jungle of the western Amazon River basin and had been carried to the islands of the Caribbean before 1492. It has diffused throughout the world but to a much lesser degree than *C. annuum*, probably because it does not store or dry well; however, it is becoming more widely appreciated by cooks and gardeners for its pungency,

aroma, and unique flavor. Although this distinctive pepper is considered to be a part of the *C. annuum* complex, some authors question its position there. The best-known cultivars are *habanero*, West Indian hot, Scotch bonnet, *ají flor*, *rocotillo*, and red savina.

- *Capsicum frutescens* (first mentioned by Linnaeus, 1753). Some authors no longer consider this semiwild species of *Capsicum* to be sustainable. It has two or more small white to greenish white flowers with purple anthers at each node and was once considered to be a member of the *C. annuum* complex, which includes three white-flowered species thought to have a mutual ancestor—*C. chinense*, *C. frutescens*, and *C. annuum*. The small fruit with cream-colored seed is always erect, never sweet, and often two or more may occur at each node. The tabasco pepper, limited to the Western Hemisphere, is the only variety of this species known to have been cultivated commercially. Easily transported by birds, the tiny varieties of wild *C. frutescens* can be found throughout the world's tropical pepper belt. The cultivated varieties are closely controlled by the McIlhenny Company of New Iberia, Louisiana. The cultivars are tabasco, greenleaf tabasco, and select.

Beijing (Peking) Cuisine  
Fujian (Fukien) Cuisine  
Guangzhou (Canton) Cuisine  
Sichuan (Szechuan) Cuisine  
Zhejiang (Chekiang) Cuisine

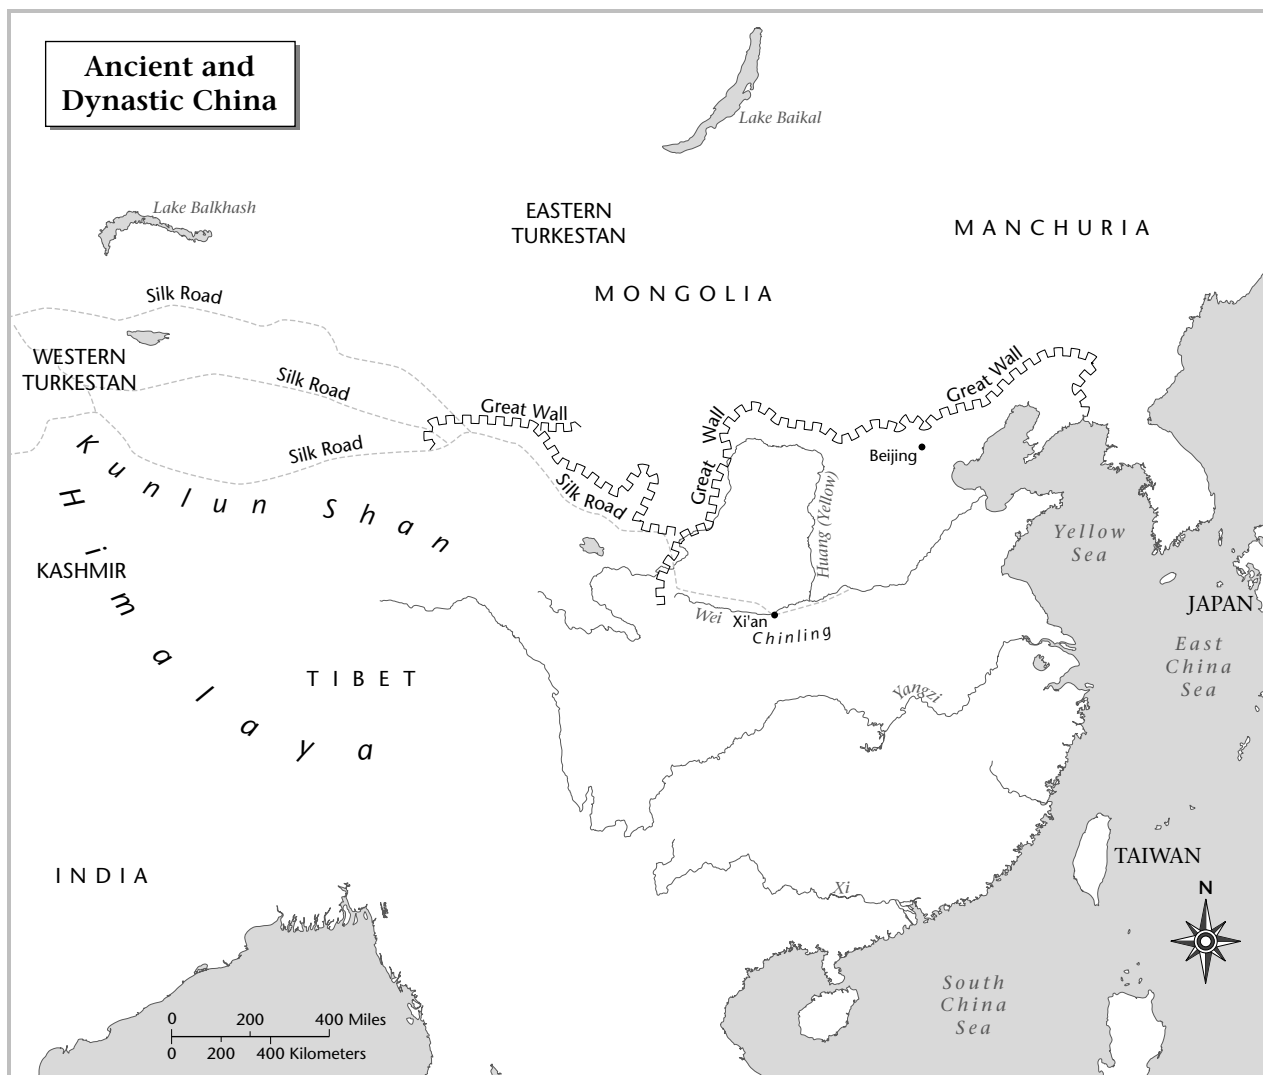

### ANCIENT AND DYNASTIC CHINA

China's foodways began to take shape at the end of the last Ice Age. The glacial period was extremely cold and dry. As it broke, from 15,000 to 8000 B.C.E., conditions rapidly ameliorated. By 10,000 B.C.E., China was becoming warmer and wetter. Plant growth increased, making agricultural innovation more reasonable. As in the Near East at the same time, agriculture seems to have

followed rapidly—stimulated, presumably, by increases in population, environmental productivity, trade, and communication.

Rice (*Oryza sativa*) was domesticated in the Yangzi Valley by 8000 B.C.E. By 5000–6000 B.C.E., it was abundant, and modern varieties had emerged: the long-grain “indica” types, the short-grain, tougher “japonicas,” and probably the sticky rices. (These latter, miscalled “glutinous,” are sticky because of a mutant form of the starch amylose.) Foxtail millet (*Setaria italica*) was domesticated farther north, by 6000 B.C.E. at the latest. It remained for millennia the staple of the areas too dry for rice agriculture. By 4000 B.C.E., it was joined by panic millet (*Panicum miliaceum*), which appeared about the same time in eastern Europe, having probably spread from China across central Asia. (The term “millet” refers to any small-seeded grain; several species of “millets” grow in China.) Foxtail millet is a more broadly

tolerant crop than rice, or indeed than almost any other grain staple. It grows best in hot summers (being a C4 plant) but is widely tolerant of different soils and water regimes. Rice, though less responsive to high heat (being a C3 plant), is an extremely efficient photosynthesizer, producing huge crops, even in cloudy conditions. C4 plants, as opposed to C3, have a metabolic pathway that allows more rapid growth in hot weather but less rapid growth in cool.

The earliest animal domestication reported so far is of pigs at Zengpiyan in Guangxi, a site dated to 7,600–9,000 years ago. The east Asian pig is the same species as, but a very different variety from, the Near Eastern one, and represents an independent domestication. Well before 6000 B.C.E., large villages with complex cultures and abundant domesticated rice occurred widely in the Yangzi Valley and elsewhere.

By 4000 B.C.E., chickens, pigs, sheep, dogs, and Chinese cabbages (*Brassica campestris*) were found widely. The

chicken is native to southeast Asia and southern China. Its first archaeological occurrence, however, is in the north, near Xian; it may have once been native there (considerably older bones of wild chicken-like or pheasant-like birds have been found), or it could have been domesticated in the south and spread northward (Anderson, 1988). Sheep possibly were independently domesticated in China and in the Near East.

After this point, China's Neolithic cultures developed dramatically. Huge, rich, intensively agricultural sites are found throughout the modern eighteen provinces, as well as in neighboring areas. (China traditionally had eighteen provinces, today the eastern and southern parts of the country; China today has twenty-two provinces.) Agriculture spread rapidly into southeast Asia; Taiwan was settled by farmers, probably Austronesian-speakers ancestral to the modern "Taiwan aborigines," by 4000 B.C.E. The pig quickly became the dominant animal. By 3000 B.C.E., it was supplying 90 percent of the meat in the core areas,

and it still supplies 90 percent of the meat in those areas today.

Meanwhile, wheat and barley spread across Asia from their domestication sites in the Fertile Crescent region of the Near East. By 5000 B.C.E. these grain crops were in Afghanistan. Their dates of arrival in China are obscure, but they were well established by 2000 B.C.E. Barley never became important, except in Tibet, but wheat was to revolutionize Chinese food in historic times, the period since 2000 B.C.E. Goats—a characteristic Near Eastern species, not found wild anywhere near China—appear about that time. Cattle, probably from the Near East, and water buffaloes, probably domesticated in or near the Yangzi Valley (and independently in India), may have been available by then, but their record is obscure. Finally, the horse, domesticated in the steppes of Ukraine and western Russia by 4500–4000 B.C.E., also reached China by about 2000 B.C.E. (the exact time being unclear).

All these introductions are related to the rise of civilization in China: the controversial “Xia dynasty” (c. 2200–1500 B.C.E.), whose existence is still sometimes debated, and the better-known Shang dynasty (c. 1500–1000 B.C.E.). These civilizations culminated a long-standing trend: the rich got richer, the poor poorer. The elite had great quantities of pork, grain, and wine, as well as other foods, while the ordinary people lived humbly on millet and coarse greens such as mallows (*Makva* spp.).

The origin of minor plant crops is poorly known. Sporadic finds of cultivated buckwheat are reported from

## THE WOK

One characteristic Chinese cooking implement is the wok (a Cantonese word; the Putonghua is *guo*). This is a round-bottomed or parabolic pan, similar to the *kuali* of India and probably historically related to it. The wok was traditionally of cast iron, but is now usually aluminum. It first appears—so far as we know—in the Han Dynasty; pottery models of woks are found on the small pottery models of stoves that—along with other household-good models—accompanied the dead in tombs. The wok is made to fit into holes on the tops of the large clay stoves of traditional Chinese houses. Today it fits well over a gas ring. The wok is designed to heat rapidly to a very high temperature. Its rounded bottom allows heat to flow up rapidly along the sides. This allows stir-frying (*chao*), in which foods are cut into small, thin bits and stirred rapidly in smoking-hot oil. As items cook, the wok is shaken, often so violently that the contents fly up in the air—cooling them quickly so that they do not burn. The goal of stir-frying is to sear the outside of the food, while leaving the inside crisp or succulent. The wok, covered and set over lower heat, can also be used for slower cooking—steaming rice, even, though flat-bottomed cooking pots are usually used for that.

## CHINESE NOODLES

Chinese noodle technology is complex. Wheat, rice, bean starch, and coarse grains are all used; wheat is most common. Noodles can be cut from a flat sheet of dough (as in Europe), extruded through a colander into boiling water, or pulled and stretched by hand. A specialty of north-central China is the swung noodle. A lump of dough is stretched out and then swung in a circle like a jump-rope; the dough stretches and gets thinner and thinner. It is folded back on itself and swung again and again. This takes a very skilled hand; otherwise the dough necks down and breaks. With skill, however, it allows ordinary wheat flour to produce a texture similar to the *al dente* texture of durum wheat pasta. (Durum wheat, the usual Italian pasta material, is virtually unknown in China.)

very early archaeological levels in Japan, but are questionable. Certainly, buckwheat was cultivated in the centuries before the Common Era in China and Japan; it probably was domesticated in northwest China's mountainous areas. A problem in interpreting China's food history is the massive disturbance to most sites. Millennia of agriculture, rodent burrowing, tomb digging, flooding, and the like have scrambled the record. Thus, peanuts—a New World crop known to have been introduced to China in the sixteenth to seventeenth centuries—turn up in Han dynasty sites, probably thanks to seed-burying rodents. By 1500 B.C.E., written records are available, but the earliest of these mention only staple grains and animals.

The history of plant domestication in China becomes brilliantly clear in the Zhou dynasty (ca. 1000 B.C.E.–221 B.C.E.). The *Book of Songs*, a collection of Zhou folk and court poetry, records dozens of plants. This work was edited in final form by Confucius himself, in the fifth century B.C.E.—according to historical records that we have no reason to doubt. Its 305 songs mention more plants than the whole of the Bible, as well as 88 animal species (some mythical). Coming from

Moon cake molds for Chinese New Year cakes. China, Ch'ing Dynasty (1644–1912), ca. 1800. Plum wood. The bat, fish, and fan motifs are symbols of good luck and prosperity. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

north China, the songs reflect a world dependent on millets. Wheat is mentioned in passing a few times. There were beans, cabbages, gourds, melons, and a huge host of vegetables and fruits. Pigs and chickens were the animals of daily use, but China was still rich in game and fish at the time.

### CHOPSTICKS

Chopsticks are first mentioned in Zhou Dynasty texts. These small sticks, used to pick up pieces of food, probably go back to the very remote past. They have conditioned Chinese food preparation; foods are virtually always cut, or made, into pieces small enough to be easily manipulated with them. Routine use spread in early historic times to Korea, Japan, and Vietnam. The Chinese name is *kuaizi*, "little quick ones," whence the English name—"chop" being pidgin-English for "fast." See sidebar on page 386.

Soybeans enter the Chinese record in early Zhou, supplementing adzuki beans, which had been grown for centuries or millennia. Soybeans originated in far north China and Manchuria, and seem to have been domesticated by non-Han peoples there, possibly the bearers of the mysterious Hongshan civilization around 2000 B.C.E.

By this time, brewing was a major art form. Chinese *jiu*, translated "wine" but technically beer or ale, was invented long before the Shang dynasty. It was made from millet, and in the south (later, at least) it was made from rice. Shang wine vessels were of heroic proportions, and all sources agree that feasting went with heavy drinking. The histories allege that the last emperor of Xia was a debauchee who had a lake of wine and a forest of meat (i.e., a forest in which strips of meat were being wind-cured hanging from trees—a sight one could still see within living memory). This is generally taken as an exaggeration by Shang propagandists after Shang overthrew Xia. Be that as it may, heavy drinking was a part of Shang feasting, and is well documented for Zhou.

A major guide to foodways are the Zhou ritual books, the *Zhou Li* and *Li Ji*. These were compiled from damaged sources in the Han dynasty (206 B.C.E.–220 C.E.), but probably reflect Zhou reality as far as food is

concerned. These sources confirm the importance of wine, mentioning many types, including herb-flavored ones. They also indicate that China, like other ancient civilizations, was deeply devoted to sacrificing animals and then eating them. Elites seem to have run through hecatombs of pigs, cattle, sheep, deer, and even horses. The trinity of pig, sheep, and cattle seems to have been dominant in sacrifice, indicating a possible indirect link with the Romans and their *suovetaurilia*. Chickens and ducks were not neglected. Old people were honored with rich, easily digestible, fatty cuts of meat, and the same favors were shown to the revered gods and ancestors. The *Li Ji* contains long passages on agriculture and on conservation.

In Han, new crops, notably grapes, came from West Asia. More important was the rise in food technology. Flour milling and oil production progressed dramatically. Bean curd and soy sauce production seem to have started about this time. (Fermented sauces were known in Zhou, but their exact nature is unclear.) Distilling of alcohol seems to have been invented in later Han. By Han, also, the idea of using food as medicine was established. The earliest surviving medical books from China are of Han date, and they have much to say about nutrition and diet therapy, always important in famine-torn China.

After Han, central Asian influences became very strong, and a flood of western foods entered China. The Silk Road, the great trade route across central Asia, linked East and West; its golden age stretched from Han through the Tang (621–960), Sung (960–1279), and Yuan (1279–1368). Persian bread, spinach, walnuts, broad beans, and even obscure herbs like fenugreek and cumin came to China, accompanied by Galenic medical concepts and Indian Buddhist foodways. Perhaps most important was the spectacular elaboration of wheat products. China, fed on millet mush and boiled rice until Han, became a land of noodles, breads, filled and unfilled dumplings, and countless other complex wheat preparations. Gradually, during this period, wheat replaced millet as the staple of the north.

The climax came in the Mongol Empire—China's Yuan Dynasty (1279–1368)—when the court in Beijing was serving dishes from Arabia, Persia, Turkistan, Kashmir, and indeed the whole Mongol-dominated world. Nomadic Mongol dishes, such as roast wolf, vied for place with Arabian delicacies such as rack of lamb marinated in saffron and rosewater (Buell and Anderson). Not until the twentieth century would the world again see such eclectic dining.

A nativistic reaction in the Ming dynasty (1368–1644) rehabilitated a Chinese food vastly more sophisticated and complex than that of Han or even Tang. The rise of an affluent middle class, especially in Sung, had led to the development of haute cuisine. Merchants and bureaucrats vied in feasting. Markets were well stocked; internal and external trade flourished. Broad regional

## TOFU

Chinese food depends heavily on a wealth of soybean products. The soybean seems to have come from non-Chinese peoples in north China and to have been borrowed by the Chinese in the Zhou Dynasty. At first it was a low-class food, but soon cooks learned how to use it to advantage. Apparently the first gourmet use was in fermented thick sauces (*jiang*), ancestral to Japanese *miso*. At some early point, brewed liquid soy sauce (*dou yu*) was invented, as well as the black-fermented soybeans popular in south China. These basic products have spawned a spectacularly diverse array of local ferment products, often using wheat flour, other bean species, vegetables, chilies, spices, or other ingredients. Soy ferments were often the only source of Vitamin B12, a necessary nutrient, in the diets of the poor. Bean curd (tofu, *doufu*) has long been said to have been invented in the Han Dynasty; there are no unequivocal references until much later, but recent evidence supports the Han date. Tofu is made by grinding soybeans with water, boiling the resulting milk, and then coagulating the boiled milk with calcium phosphate, alum, or some similar coagulant substance. The result is highly nutritious, and, if made with a calcium substance (as it almost always is), a very important calcium source. The oil and certain nutrition inhibitors go out with the waste water, leaving a low-calorie, high-nutrient product. It has served as the protein source of the poor through much of history. The skin that forms on the boiling milk, the lees, and other related products are all used, especially in vegetarian cuisine. With rising affluence, tofu consumption has declined in China—but risen explosively in the health-conscious western world. H. T. Huang provides a definitive history of soybean products in China. (See also Anderson, 1988.)

styles had long been important—the meat-eating northwest contrasted with the fish-eating east and south, for instance—but now every city and many a town developed its own distinctive dishes and food specialties. Tea and distilled liquor had joined wine as common drinks, and gourmetship in tea and wine took extreme forms. Tea might be made, for instance, with water obtained from melting snow that fell on flowering-apricot blossoms; the carnation scent of the latter very delicately perfumed the tea. Nor were the less fortunate forgotten; a Ming prince, Zhu Xiao, compiled an excellent and thorough guide to famine foods in the early 1400s, and had it distributed to local governors throughout the country.

The most important food event of Ming, however, was the rise of sea trade, and especially the coming of contacts with the New World. Much of China, especially in the south, was not suitable for rice or wheat. Millet was at best a poor substitute. Suddenly, maize, white potatoes, and sweet potatoes appeared. Maize was common before 1600.

The great spread of New World crops came in the subsequent Qing dynasty (1644–1911). Sweet potatoes reached China by the late 1600s, and white potatoes by 1800. They continue to spread. Peanuts, tomatoes, chiles, guavas, and other New World crops revolutionized nutrition by introducing productive, easy-to-grow, nutrient-dense foods. Chilies, in particular, are extremely rich in vitamins and minerals; they, and the other New World crops, were critical in allowing the population explosion that has taken China from fifty million people in early Ming to today's 1.25 billion. Travelers in nineteenth-century China remarked on the availability and cheapness of a varied, nutritious diet.

Yet, China remained the “land of famine,” in Walter Mallory's telling phrase. Deforestation and consequent flooding, overhunting, overfishing, and other environmental devastation led to disasters. Unfortunately, the pace of abuse greatly accelerated through the twentieth century (Brown; Edmonds).

### BEIJING (PEKING) CUISINE

The cuisine of the city of Beijing is rooted in the broader tradition of north Chinese food. As the capital of China for most of the last eight hundred years, Beijing has been the beneficiary of two additional forces. First was the development of an imperial court cuisine perhaps unrivaled in the world. Second, as political center of China, Beijing has been a magnet for people from all over the world. Inevitably, they bring their foodways with them. The Mongols who established their court there in the Yuan dynasty brought barbaric delicacies such as wolves and swans, and today MacDonald's hamburgers are familiar.

Beijing occupies a dry, dusty region, oppressively hot in summer, bitterly cold and windy in winter. Nearby hills give relief from the summer heat, but there is no escape from winter's chill. Today, and even to some extent in the historic past, smoke and soot densely cover

Nineteenth-century print of daily life in China. © ARCHIVO ICONOGRAFICO, S.A./CORBIS.

the city, adding to the discomfort. The familiar foods of China's warmer, wetter regions, such as rice, fish, and subtropical fruits and vegetables, were rare luxuries until very recently.

Beijing's basic foodways can stand as exemplar for the north Chinese style of cooking. This style is found throughout northern China, with outstanding substyles in Shandong and Hebei as well as Beijing. It is China's simplest, and in the northwest—Shaanxi and Shanxi especially—it can become very simple indeed. These areas were, and in some areas still are, hunger zones, hard hit by famine. Often, only two meals a day are eaten, and coarse grains (maize, sorghum, buckwheat) are often important foods. Even so, they have their specialties, including Shanxi's outstanding vinegar.

North China produced very little rice until recently. Wheat and soybeans are staples. In early times, millets, especially foxtail millet (*Setaria italica*), were staples. Millet has now been almost entirely replaced by maize. This New World crop came north from southern China in the Qing dynasty, but was rare and unpopular. People correctly saw that millet was much more nourishing. In the twentieth century, however, vast increases in the productivity of maize have tipped the balance; foxtail millet has not benefited significantly from Green Revolution research. However, maize is still unpopular as a human food, and is largely fed to animals. Today rice is also produced well north of its historic range, and has become more familiar in the area. At the same time, the traditional oilseed, oil cabbage (rape cabbage), has been supplemented by sunflower, maize, and soybean. Vegetables, until recently, were also rather limited. In winter there was little beyond the Beijing cabbage—the cylindrical-headed form of Chinese cabbage, with pale leaves and greatly enlarged, crisp leaf bases. A conscious effort has recently been made to diversify winter vegetable availability. Melons were major fruits, especially the watermelon, extremely popular in summer for its cooling and diuretic qualities as well as its sweet taste. Their seeds were a popular snack, to the point that some varieties of watermelon were bred only for seeds, having many large seeds and very little flesh. In season, peaches and jujubes ("Chinese dates," *Zizyphus Zizyphus chinensis*) were common. Walnuts, lotus nuts, and other fruits and nuts were luxury items.

As in most of inland China, the pig was the main meat source, but beef and even lamb (or mutton) were frequent—the latter especially in Hui (Chinese Muslim) neighborhoods, which are extensive and are famous for their food. Chicken and duck were common, but the ordinary citizen saw them only at very special events.

Standard northern flavorings are ginger, sliced scallions, garlic, sesame oil, Chinese "wine," and soy sauce. Spices were traditionally quite rare. Coriander leaves

### LAMB WITH EGGPLANT

Adapted by the Mongol court for Beijing use.

- 1 medium-sized eggplant
- 8 oz. lamb stew meat, with some fat
- 1 small onion, chopped fine
- Dried mandarin-orange peel, 1–2 pieces (available in Chinese groceries as "dried orange peel")
- 1–2 cloves garlic
- 4 oz. yogurt
- 2 tsp crushed mint

Cut eggplant in half and remove central seedy part. Chop this, mix with lamb, onion, orange-peel, and stuff the eggplant. Steam or bake. Make a sauce: mash garlic, mix with yogurt. Put this over the eggplant and then sprinkle with the dried mint.

This is a version of a dish still common in Turkey and neighboring areas.

—Buell and Anderson, pp. 313–314

### CARP WITH GINGER AND CORIANDER

Here is a Chinese dish from the same source.

- 1 carp, about 2 lb.
- Flour for dusting
- Bean flour batter, enough to cover fish pieces
- 1 tsp ground coriander
- Salt to taste
- Vegetable oil
- Fresh (sprouting) ginger
- Cilantro (coriander leaves)
- ½ tsp turmeric (or safflower)
- Radish slices

Scale the carp. Make a batter with the flour, bean flour, ground coriander, and salt. Batter the fish, let sit for an hour, and fry. Garnish with ginger (shaved), cilantro, turmeric (or safflower), and radish slices fried briefly. "Adjust flavors with onions" (apparently meaning: garnish with green scallions, slivered).

—Buell and Anderson, p. 308

## HOW TO USE CHOPSTICKS

For Westerners accustomed to knives and forks, the proper handling of chopsticks is one of the most puzzling and awkward aspects of Chinese table etiquette. In the past, the way someone held chopsticks conveyed a great deal about his or her education and social class. Once mastered, chopsticks are much easier to use than knives and forks since the food is already cut up before it is served. These directions, illustrated by the accompanying drawings, describe the way to hold chopsticks in a manner generally acceptable throughout Asia.

Step 1. Place a chopstick in the right hand between the thumb and index finger and rest it on the ring finger. The narrow end of the chopstick, the end used to pick up food, should point down. Slide the chopstick so that when it is held between the thumb and index finger about two-thirds of it is below the fingers.

Step 2. Place the other chopstick between the index finger and thumb, with the narrow end resting on the third finger. Hold the chopsticks firmly.

Step 3. Use the second chopstick to grasp food by pinching it against the first chopstick (which remains stationary). The tops of both chopsticks should be kept even so that they can be used like large tweezers. Never stab food with a chopstick.

Practice before going to an Asian restaurant. If there is an Asian store in your community, visit it to see what types of chopsticks are being sold. There are many styles, and some shapes are easier to use than others (square chopsticks are less likely to slip while smooth plastic ones can be difficult to hold in place). A true connoisseur will own several sets of beautifully ornamented chopsticks, which are kept in their own cases.

*William Woys Weaver*

(cilantro), introduced from the Near East in early medieval times, are a frequent flavoring or garnish.

The long, harsh winters forced the development of a sophisticated pickling and preserving industry. Pickled vegetables, sausages, dried meat, salted foods, and preserved fruits are important.

The court, of course, had far different fare. Exotic delicacies were the rule. Perhaps only the Mongols actually ate wolves. According to a more authentically Chinese tradition, the "eight delicacies" were served—the list

is variable, but includes such things as camels' humps, apes' lips, and bears' paws, as well as various mythological animal parts. At least the bears' paws were in fact eaten; they are cooked long, into a gelatinous state. The appeal of such items is their rarity rather than their taste, but bears' paws are relished also by actual bear hunters in Siberia and north Canada. More prosaic but presumably much more common were rare species of mushrooms, bamboo shoots, and other vegetable foods, as well as complex and detailed preparations of ordinary animals such as chicken, duck, and fish. Dishes from the remote reaches of the empire, such as central Asia and Tibet, often graced the table, especially when dignitaries from those areas were being entertained. From southeast Asia came preservable exotica such as birds' nests (edible nests of swifts of the genus *Collocalia*) and sea cucumbers. Thus the court showed its cosmopolitan, world-ruling power

as well as its hospitality. Many imperial recipes are preserved, and restaurants occasionally arise that re-create them.

History records that many emperors ignored the elaborate dishes and preferred simple fare. This is a formula, meant to indicate the virtue of the emperor; simplicity, indifference to vain show, and empathy with the ordinary people are virtues in all Chinese religious and philosophical traditions. However, the story is told circumstantially enough of some emperors to be apparent literal truth. In these cases, it stands as a telling comment on the quality of the formal service. Kenneth Lo, in *Peking Cooking*, records some imperial menus and other lore, including cutting remarks on the quality of the pompous feast fare. The last emperor, Aisin Gyoro Puyi, commented: "One big tasteless spread. All show and no flavour!" (1971, p. 24).

More usual fare—the fare of the vast majority, including, perhaps, those emperors—was based on wheat products. Noodles in soup, large steamed breads, and filled dumplings were staples. The large breads, usually chemically leavened, were called *mantou*, which means "barbarian heads." Forms of this word are used from Korea to Greece; the word may actually be from an Altaic language, or it may be Chinese from the start. It used to refer to filled dumplings, and still does everywhere except in China, but at some obscure time the Chinese term came to refer to solid wheat loaves. Today, large filled dumplings (typically with leavened dough) are *paozi*. Smaller filled dumplings are *jiaozi*, a term limited to China, but denoting dumplings virtually identical to the *mantu* or *manti* of Korean, Turkic, and Greek kitchens. They are also clearly related to the *kreplachs*, *pelmeny*, and *vareniki* of eastern Europe, and to many other steamed or boiled dumplings of Eurasia. The complex history of these foods is still unclear.

The rich had rice congee: rice cooked in considerable water to make a thin porridge. The poor had an equivalent in porridge of millet, soybean meal, or wheat meal. Millet porridge, especially, was the most ancient foodstuff, having been prepared since earliest Neolithic times. It could be thick or thin. Often it was plain, but it could be flavored with sweet or savory ingredients. Cakes of coarse corn meal stood at the bottom of the prestige scale.

For centuries, Beijing has had countless eateries, from expensive and exclusive restaurants to food carts along the streets. Tea houses flourished everywhere, serving varying grades of tea along with snacks. These establishments varied from exclusive and refined, with the finest tea and foods, to rough stands for ordinary workers. They served as meeting houses, poor folks' offices, and centers of political and social activity. Also common are food stalls and small, inexpensive restaurants selling noodles and dumplings. The food at these is consistently fresh and good, but not notably diverse.

Once chopsticks are mastered, it is easy to remove slippery dumplings from a large common bowl, as this family is doing in a Hong Kong restaurant. © RANDY FARIS/CORBIS.

As elsewhere in China, freshness is an ideal. Fish and poultry are sold alive whenever possible, and even larger animals may be. A new load of vegetables or fruit commands a high price, which may drop by the hour if the sun wilts the produce.

Ingredients in Chinese food are cut or otherwise prepared in bite sizes for ease in handling with chopsticks. Since earliest recorded times, eating large hunks of food was considered barbaric.

More ambitious restaurants have far more varied offerings. Traditionally, restaurants specialize in one type of cuisine. Some offer the dishes of a particular province or ethnic group. Others may focus on only one dish. Several classic Beijing dishes are so elaborate, and so popular, that restaurants focus solely on them.

The most famous such dish was, and is, Beijing duck. Ducks were domesticated in north China, and the most successful variety worldwide remains the "white Pekin"

(or, more recently, its improved descendants). A proper Beijing duck is carefully raised from hatching onward. It is specially fed to give it the right amount and flavor of fat and meat. Killed at some three months of age, it is hung for a while, then inflated to separate the skin from the flesh. Preparation is simple: it is seasoned and roasted. As is true with ducks and with marinated pork slabs in much of China, Beijing duck is hung on a hook to roast, so that all sides are evenly cooked. Then the flesh and skin, cut up, are eaten rolled in small wheat pancakes, with fermented sauce (several variants are allowable) and slivered scallions. Some gourmets would eat only the skin, leaving the meat for servants.

Other dishes indicate the strength of Muslim and central Asian influence. Most pervasive are *shaobing*. These are small raised sesame breads, traditionally cooked Iranian style in a small *tandoor* oven. They are miniaturizations of Iranian *nan*, and seem to have been introduced in the Tang dynasty, when the Iranian court took refuge in China from the Arab armies that conquered Iran for Islam. Iranians were to be found on street corners everywhere in Xian (then Chang'an) selling these breads (see Schafer, 1963), which were soon nativized as Chinese fare. In Beijing today, they are often stuffed with meat that is slivered and then grilled or stir-fried. One such dish, of presumptive "barbarian" origin, is "Mongolian barbecue." This dish is not necessarily Mongolian in origin; it seems more likely a modern evolution from traditional Muslim Chinese dishes. It involves meat sliced very thin, drenched in a selection of piquant sauces, and grilled on a metal brazier over a high flame.

Another famous Muslim dish that has its specialty restaurants is lamb hot-pot. Chinese diners love to do their own cooking. Most often, this is done by dipping very thinly sliced ingredients into boiling stock at the table. The slices cook quickly, and flavor the stock, which is eaten as soup at the meal's end. Every province has its own versions of this hot-pot meal; Beijing's is based on lamb. The lamb has to be sliced evenly and very thinly. Chinese cooks spend years learning how to slice properly, and this dish provides a rigorous test of their accomplishments.

From farther afield come such dishes as the sweet-sour fish of Hebei. Made from fresh-water fish (usually species of carp), this is said to be China's best version of the dish. Shandong restaurants provide that province's superior dumplings and fish dishes.

In recent years, Beijing has added American fast foods to its diverse scene. Yan Yunxiang (1997) reports that McDonald's was, in the 1990s, the place to be seen—at least, many young people thought so. Young men would spend hours over a cup of coffee—all they could afford—simply to show they were sophisticated and cosmopolitan enough to be there. McDonald's, the symbol of bottom-scale eating in its native land, thus took on the prestige that, in that land, is reserved for exclusive Con-

tinental-style restaurants. More recently, Starbucks and other chains have been added to the youth scene.

#### FUJIAN (FUKIEN) CUISINE

The foods of southeast China are exceptionally diverse. Fujian, moist and both semitropical and tropical, is in that region and sixty-eight nautical miles across the straits from Taiwan. For those who divide Chinese food by compass points, Fujian, also spelled Fukien or Fu Chien, is distinctly eastern and has culinary similarities with nearby regions. Its foods are influenced by rivers, long coastlines, and interior rugged mountains, some reaching to the sea. This region, its landscape and its foods, is called *shan shui*, meaning mountain and water. It is one of China's five outstanding traditional cuisines, the others originating from the Guangzhou (Canton), Honan, Shandong, and Sichuan provinces. Fujianese foods are easily recognized: their rich stocks and sauces are used in a plethora of thin and thick soups. Two or three soups are commonly consumed at main meals and five or six at banquets. Many main ingredients are marinated in wine or the leftover red wine sediment called *lees* or *hung jiu*.

With a population of almost thirty million people and an area of forty-eight thousand square miles, the foods of Fujian—also called Min—are common wherever the Min or Wu dialects are spoken. They can be found in Fujian and in the southern Guangdong province in Shantou or Swatow, where many descendants of a well-known statesman exiled during the eighth century fled. This variation of Teochiu, Chiuchow (also spelled Chao-chou and Chaozhou), is considered the finest cuisine. Concentrating on foods of the sea, it uses many season-

ings, fish sauces, citrus marmalades, and satay-type sauce pastes. Every Fujianese food is loved locally, by those living on Hainan Island and by peoples in nearby areas. It is missed by more than 2.5 million Fujianese living overseas. Although popular throughout China, this cuisine is little known outside of the country.

The foods of Fujian are closely related to Taiwanese cuisine as many Fujianese fled there during several disruptive historical periods. This ancient cuisine, its origins predating 135 B.C.E. when the state of Min Yue was established in the Fujian province, has food roots in ancient Hakka migrants from northern provinces, aboriginal groups, and local Han peoples. With only 10 percent of its land arable, the remaining extensively cultivated areas grow a reasonable amount of rice, wheat, and sweet potatoes. They also grow fruits, soybeans, peanuts, and other oil seeds; people eat these agricultural products year-round, fruits included, because the region specializes in drying and preserving them. Sweet potatoes were not an important dietary component until they helped alleviate famine during Sung times (960–1280 C.E.) and again in the late 1500s. A shortage of rice propelled interest in this tuber, shredded and dubbed “sweet potato rice.” Wheat foods also substituted for rice, and currently both are major dietary components in the region.

The sweet potatoes are roasted, boiled, and dried, used as snacks and meal components, and made into flour. Along with wheat, they are eaten in amounts equal to rice and used to make noodles, pancakes, dumpling skins, and other foods. Wheat and sweet potatoes are used to produce noodles in every imaginable shape. More are eaten here than in any other Chinese province; they are frequently served in soups when their solid content is finished. Noodles are also served plain, in stir-fried dishes and soups and stews, and transformed into batters. The latter is called “swallowskin” and is made from thin poured noodle batter. The batter, or *kuopien*, is cooked in a wok, and soup is added to it when a soft crust is formed. Swallowskins may also be served plain, have dried powdered pork or wine lees as ingredients, and can be used as wrappers for dumplings and fried foods. Some batters are made only of egg whites. These are called *kao li* and often have foods buried underneath.

*Chou*, better known also as *juk* or *congee*, is a popular southeastern breakfast-type rice soup. Other beloved Fujianese foods are fish balls, turtle meat, and a large variety of fungi including black or silver (white) cloud ears called *mo-er* or *yin-er*, respectively. Dishes are made with coagulated pig or chicken blood, with foods from local waters, and with chicken, pork, duck, and some goose. It is not uncommon in this province to be served a bird’s nest or shark’s fins as a main course, served as a thick stewlike soup. Many foods are cooked more slowly, fried with lard, and seasoned more liberally than in neighboring provinces. Soy sauce, with famous varieties made from local water, is employed sparingly in dishes, but large amounts are used in dipping sauces.

Contrary to practice in other provinces but similar to that in Guangzhou, tea is commonplace at meals. Grown in the north, it is preferred black, but more accurately called red for the color of the brew. The most popular variety is local; it is called *tit guan yin* or “Iron Goddess of Mercy.” Local dishes are sweetened with sugar cane grown in the south, vegetables harvested wherever they can be grown, and animals raised where crops do not prosper.

Fujianese foods are typically served in three daily meals; they are easily recognized. Mornings start with rice soup and other small dishes or seasonings for the *juk*, two to three soups accompany other dishes at main meals, and five or six and an equal number of other dishes make up a banquet. Other than the breakfast *chou* or *juk*, soups may be clear, with contents, or thick and stewlike. Dipping sauces accompany other dishes, such as garlic crushed in a vinegar base if the main protein is poultry, or maltose if it is fried fish. Dishes and soups are based on complex stocks, maybe a sweet and sour sauce. Some are highly colored, many red from the marinade of red wine lees.

Fuzhou, also transliterated as Foochow or Foo Chow, was founded in 202 B.C.E. Meaning “happy city,” this provincial capital on the Min River is blessed with more than a hundred different kinds of freshwater fish. It enjoys Fujianese and Fuzhou dishes cooked with fermented red wine lees, dumplings wrapped in swallow skin, noodles made with powdered pork, and meat and fish in one dish—sometimes one ball as in fish balls stuffed with meat in soup. Fermented fish sauces are used, as are different types of soy sauce, an influence from other southeastern countries that, in turn, were influenced by Fujian.

Xiamen, once called Amoy, is the second largest city in Fujian. Both are important up-river port cities sheltered from typhoons; they helped the province become a major maritime trading center. Known for their *popia*, Xiamenese people love this pancake. It is commonly filled with cooked meat and vegetables such as bean sprouts, garlic shoots, carrots, and bamboo shoots. Seaweed may also be added and the mixture flavored with hot mustard and/or plum sauce. Other popular dishes with roots in this city are stir-fried Xiamen noodles and Xiamen spring roll. Both are made with carrots, bean sprouts, peanuts, and grilled seaweed strips.

Well-known Fujianese dishes include diced and fried wine-marinated pork, steamed chicken in preserved tofu, drunken spare ribs, sweet and pungent litchi pork, deep-fried eel in wine lees, oyster omelet, stir-fried razor clams with ginger, hot and sour squid soup, duck tongue with white and black fungus, fried peanuts, and dried longan soup with lotus seeds. Also well known is *chi ping*, a Hainanese chicken-rice dish. Peace noodles are served everywhere on the first day of the first lunar month and eaten during *Ao Jiu* festival that same month. Another special dish is “Buddha Jumping Wall,” a multiboiled

thick casserole with shark's fins and ten other ingredients. Herbal soups are popular, too, and made with peony or rheumanna root, angelica (*sinensis*), star anise, wolfberry (*Lycium chinense miller*), cassia bark (*Cinnamomum aromaticum*), or a member of the prickly ash/fagara family (*Zanthoxylum avicennae*). In addition, they and other herbs are used as tonics, concentrates, and pastes.

Current literature divides China into many culinary regions, regional or provincial. Almost all include Fujianese food, whose essence may be found in its plethora of soups, sauces, vegetables, seafood, fruits, mushrooms, herbs, preserved fruits, and a special treat called "Tribute Candy." This after-dinner or snack sweet is a blend of baked peanuts ground into maltose or ground peanuts wrapped in a paperlike layer made from glutinous rice. Served with fresh fruit at the meal's end, it is enjoyed by everyone who adores sweet and tasty foods.

#### GUANGZHOU (CANTON) CUISINE

Cantonese food has attracted a world following for its quality and variety. As to the former, a Chinese proverb says that one should "marry in Suzhou, live in Hangzhou, dine in Guangzhou, and die in Liuzhou," since these cities have, respectively, the prettiest girls, best views, best food, and best coffin woods. As to the variety, Chinese say that the Cantonese "eat everything with legs except a table, and everything with wings except an airplane."

Cantonese food is, broadly speaking, the food of Cantonese speakers. Cantonese is a separate language (though not dialect; there are, rather, several dialects of Cantonese) spoken throughout most of Guangdong province and well into Guangxi, and also by migrants who have radiated throughout the entire world. More narrowly, Cantonese food is the food that reaches its highest level of development in Guangzhou (the capital city of Guangdong) and in late-twentieth-century Hong Kong. The north parts of Guangdong are inhabited by Hakka and Teochiu people who speak other languages within the Chinese family; they have their own distinctive cuisines. Much of Guangxi, especially in the west and south, is inhabited by Zhuang and other Thai-speaking minority peoples, who also have their own cuisines. This leaves Cantonese food and language to some fifty million or more people.

This area is roughly coterminous with the part of China in which rice agriculture has always been most intensive. Lowland paddies produce up to three crops a year, and have since imperial times. Yields in the early twentieth century reached 2500 kg/ha. Today, with new varieties and intensive fertilizing, yields reach four or five times that figure. Nowhere else in China does rice so dominate the scene. Therefore, rice traditionally supplied some 90 percent of calories in the typical diet, and was the only true staple food. Other starchy foods—notably sweet potatoes and maize, since their seventeenth-century introduction from the New World—were mere famine backups.

In traditional times, a tightly integrated farming system developed, which combined this intensive rice agriculture with aquaculture, duck and pig rearing, and fruit and vegetable gardening. Every crop was fitted tightly into its place. For instance, ducks were taken by boat from field to field; they would be turned into a field when the crops were too old to be tempting food. Instead, they would eat the snails and insects, and leave fertilizer behind. Several species of fish were raised, each eating a

different set of natural pond life-forms. Pigs and chickens were raised on leftovers and on items inedible to humans. Frogs and other wildlife were caught and eaten. What escaped the system and washed out to sea was cycled through shellfish and finfish. Nothing was lost and nothing was wasted. This system, along with related systems in southern Japan and central Java, was the most intensive and productive agriculture in the world before the rise of green revolution crops in the mid-twentieth century.

In coastal and delta areas, the most important animal protein is fish. Thousands of species of marine life occur and are utilized. Recently, overfishing has made aquaculture relatively more important. Away from the coast, pork is overwhelmingly the major meat, with poultry reserved for festive fare and other meats quite rare. Dogs, cats, and game animals are eaten, but not often. Soybean products, including bean curd, soy sauce, and fermented black beans (*tau si*), probably supplied more protein in the past than meat did. The most abundant vegetables are Chinese cabbages (many varieties) and the onion family (five species, in order of importance: onions, green onions, garlic, garlic chives, Chinese leeks). Also important are lettuce, tomatoes, potatoes (both white and sweet), taro, bamboo shoots, and dozens more. Condiments include vinegar, strong mustard (from *Brassica juncea*), white pepper (not black), chili sauces, and, above all, soy sauce and its variants. Food is almost unthinkable without soy sauce. Rice by itself is not a meal, but rice with soy sauce is, and for the poor in earlier times it was, often the only meal of the day. Distinctively Cantonese, and a real marker of the cuisine, are *tau si*, soybeans boiled, salted, and fermented such that they turn black and acquire a strong meaty flavor.

Freshness, tenderness, and delicate subtle flavor are ideals. Relatively young animals and vegetables are preferred to old ones. Fresh items are always preferred. Not only are fish kept alive until wanted; they are preferred if kept alive in clean ocean water (rather than tanks), and they are sometimes taken at a dead run to the kitchen, so as not to lose a moment outside the water. Poultry was traditionally fed specially on high-quality foods. (Pigs, however, were fed on anything available.) The quality of the ingredients was once the most important dimension for evaluating food and restaurant quality. The goal of cooking was to preserve the essence of the fresh food item by cooking it quickly in a simple yet perfectly calculated way. Split-second timing was characteristic; a change in the sound of boiling or frying signified doneness, and the item was instantly whisked off the flame. Items are often briefly boiled before being stir-fried, so they would be tender in spite of quick frying.

Traditional food preparation includes salting and drying fish and vegetables. Small shrimps, salted and self-digested, produce a paste that is liked by some individuals. Pork sausages of various kinds are prepared; the most

A set of brown glazed soup pots reinforced with wire to prevent expansion and cracking. Pots of this kind are used all over China for making both stews and soups. Whole ducks or chickens can be placed inside the pots of larger size. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

popular, *laap cheung*, traditionally includes rose-flavored alcohol. Unique to Cantonese cuisine is pork, roasted and marinated while hanging from forks in a tandoori-like clay oven. This dish is now usually baked in a more modern style, but retains the name *ch'a siu*, “fork-roasted.”

The diet was based on rice eaten with a vast variety of vegetables and animals. The basic division in the diet was between *faan*, cooked rice, and *sung*, a word unique to Cantonese and referring to anything cooked to eat with or on the rice. Rice is regarded as the perfect food—indeed, a true “cultural superfood”; people feel they have not really eaten unless they have eaten it, and the standard Cantonese greeting around mealtime is “have you eaten rice yet?” (One always answers “yes,” because if one says “no” the greeter is more or less duty bound to offer food. This custom harks back to the old days, when poverty was widespread and eating was by no means a regular thing.) Foods not eaten with rice are primarily mere snacks, sometimes called *siu sik*, “small eats.” These include fruit, sweets, and the elaborate snacks called *tim sam*, “dot-the-hearts,” which have evolved into the “dim sum” of global Chinese restaurants. The only substantial fare that does not involve rice are the noodle dishes, and even the noodles are sometimes made of rice—though wheat and wheat-and-egg noodles are commoner. Noodles are usually boiled in soup, or boiled and then stir-fried with vegetables and meat (the famous *ch'ao mien* or “chow mein”).

The usual breakfast is tea with fried pastries and/or *juk* (congee), a small amount of rice boiled in a lot of water, producing a thin mush. It is eaten with peanuts, salt vegetables, soy sauce, or similar strong-flavored foods mixed in. Special occasions call for a long, lingering breakfast over tea and *tim sam*. This ritual, known as *yam*

*ch'a* "drinking tea," has recently migrated to brunch or even lunch hour, and become a weekend fixture.

The main meal of the day can be at noon, midafternoon, or evening. It is based on a large amount of cooked rice. With this, typically, one finds a steamed dish and a stir-fried dish, and perhaps another steamed dish. Steamed fish and stir-fried vegetables would be a typical combination. It is common to prepare a four-dish meal in one pot by putting small saucers of raw foods on top of the rice, and simmering all in a closed pot; the other dishes steam while the rice boils. Almost invariably, there is soup, usually at the end of the meal. Water is known to be unsafe to drink unboiled; boiled water by itself is neither tasty nor nourishing. Tea is expensive. Soup, in contrast, is known to extract the nutrient values of foods, and can be made from tough vegetables and other economical items. It is thus the preferred way to take liquid.

The other meal (lunch or casual supper) will normally be noodles in soup, or a similar substantial but unassuming dish.

Banquets involve large amounts of meat and fish, and little or no rice. Whole fish and other impressive seafoods are usually the most expensive and prestigious items. Pork and duck are normally present. Special ritual foods abound, and include whole roast pigs and stews of great pieces of meat. Men are the cooks for these large sacrificial dishes. In general, women are the cooks in China, but men are the restaurant chefs, specialists, and preparers of large ritual meals.

Desserts are unimportant, simple fruit being generally preferred, but some sweets are prepared. Notable are small cream tarts called *taan t'a*, "egg tarts," probably English (via Hong Kong) but identical also to Portuguese *pastel de nata* and thus perhaps borrowed through Macao. Cookies and fruit are traditional gift items.

An important aspect of Cantonese food is eating for medicinal value. Dozens of foods are eaten largely for perceived healthy qualities: snake for warming during winter, watercress for cooling, wild ducks or pork liver for strength and energy (their high available iron content explains this), certain herbs for cleaning the system, and—of course—chicken soup for almost everything. In Chinese medicine, foods are heating, cooling, or neutral. Heating foods—high-calorie, fatty, reddish, or spicy—make the body hotter, or give rashes and sores. Cooling foods—very low-calorie, watery, sour, or cool-colored—make the body cooler, and in excess lead to loss of energy and strength. Neutral foods are balanced; cooked rice, noodles, and white fish are examples.

Chinese wolfthorn fruits (*kau kei ji*) and leaves (*kau kei ch'oi*) are the highest in vitamins and minerals of any common food, and are thus used as nutrition supplements. In Chinese medicine, all foods have significance for health. Food grades into medicine. Many foods, such as the wolfthorn, are eaten purely for their medicinal value. White fungus, dried scallops, and other items are

on the borderline. Even medicinal herbs such as ginseng could be called foods. Food is the first recourse when an individual feels less than well. After childbirth, women eat foods perceived as strengthening and warming; modern analysis shows these foods to be high in iron, calcium, and other minerals, in vitamins, and/or in easily digestible protein. It is well known that such foods restore health and benefit milk production.

There are regional variants of Cantonese cuisine—often coterminous with dialects of the Cantonese language. The T'ai Shan area, for instance, is home to the Toisanese dialect, and to such dishes as *tsap seui* "miscellaneous leftovers." This became the infamous "chop suey" of third-string Chinese restaurants in the western world, but it began life as a good if humble dish among the specialist vegetable farmers of the area. At the end of the day, they would stir-fry the small shoots, thinnings, and unsold vegetables—up to ten species in a dish!

Changes in recent decades have been dramatic. Affluence has eliminated the famine and want that drove many within living memory to live on sweet potato vines, outer leaves of cabbages, and tiny shellfish gathered at low tide. A greater variety of food is available. Standardization has meant better and safer processed foods. Meat is relatively cheaper, and consequently more used. On the other hand, mass production in agriculture, and volume feeding in huge restaurants and chains, has spelled near-doom for the concern with quality ingredients. Much more oil, sugar, and salt is used now than forty years ago. Monosodium glutamate (isolated in Japan in the early twentieth century) spread into Cantonese cooking via overseas restaurants, and is now almost universal. Hamburgers, fried chicken, and other American fast foods abound in south China, and have inspired adaptations and hybrid descendents.

Cantonese cooking has spread throughout the world, and is the main ancestor of the simplified "Chinese cooking" found in small Chinese restaurants everywhere. Humbler variants on this theme include the "takeouts" of England, the "chop suey joints" of North America, and the "chifas" (from Putonghua *chi fan* "eat rice"[?]) of Peru. Much more sophisticated and elaborate Cantonese restaurants exist overseas, especially in major American and Australian cities; those in Vancouver, San Francisco, Sydney, and elsewhere now rival Hong Kong and Guangzhou in quality. These diaspora restaurants have affected the homeland; the fortune cookie, invented in California around the end of the nineteenth century, was only beginning to reach Hong Kong in the 1960s, but is now found worldwide.

In the future, as world population rises, the intensive, high-yielding, efficient food production and processing system of southeast China will become a more and more attractive model.

## SICHUAN (SZECHUAN) CUISINE

What is widely called Sichuan cuisine is part of a broader suite of culinary traditions more properly regarded as the cuisine of west China. Traditionally, Chinese schematize the world in sets of five. In this scheme, the great cuisines of China are those of Beijing, Sichuan (or Hunan-Sichuan), Shandong, the Yangzi delta, and Guangdong. It is, however, more ecologically and geographically accurate to divide Chinese cuisine into north (including Beijing and Shandong), east, south, and west.

Included in the western group are the cuisines of Hunan, Sichuan, Yunnan, Gueizhou, and (marginally) Hubei. Boundaries of culinary regions do not correspond exactly with the boundaries of provinces. Yunnan and Gueizhou have large aboriginal populations with distinctive foodways. Parts of Hubei and other provinces shade off into other culinary regions.

West of Sichuan lies Tibet. This vast highland produces few foodstuffs. Barley and buckwheat, which grow at high elevations, are staples. Particularly important to nomadic herders and other travelers is *tsamba*: barley parched (roasted in the oven) and ground into meal. This can be mixed with tea, milk, or broth to provide an instant meal. Dairy products are extremely important and are often made from yak milk. Butter is not only a food but also serves as sunblock, sculpture medium, gift item, and more. Vegetables are few; wild herbs are used. Feast dishes include dumplings and meat dishes related to those of China and central Asia and—especially in the south—mixed dishes with Indian and Nepalese ancestry.

Several small ethnic groups related to the Tibetans live in mountainous parts of Sichuan. Many rely on thick cakes of buckwheat, maize, or other montane grains. Most share the Chinese avoidance of dairy products, but some—those near Tibet and dependent on herding—use dairy products heavily.

North of Sichuan is Shaansi, which has its own foodways. These are simpler than Sichuan's and are dominated by wheat products: noodles, dumplings, buns, and much more. Lamb is popular. Vegetables are rather few,

and spicing is simple; chilies are used, but not so much as in Sichuan. The leading city of Shaansi is Xian, which was the capital of China—under the name Chang'an—for many centuries; it finally lost out to Beijing in the Liao Dynasty. Xian has a wide range of dishes, many of them using wheat, lamb, onions, and vinegar. (Vinegar is even more a specialty of Shansi, Shaansi's eastern neighbor.) Tang Dynasty texts already reflect this relatively simple cuisine. Central Asian influences were strong in those days and are still apparent (especially in the importance of lamb), though the popularity of dairy products—well-attested in texts between 400 and 900 C.E. has waned considerably.

The specifically west Chinese culinary world is that of the densely settled urban and agricultural regions of the middle and upper Yangzi River drainage and the plateau country south of it in Yunnan and Gueizhou. Most densely populated and agriculturally rich are the Yangzi valley and Dongting Lake area of Hunan and Hubei and the Red Basin (named for its red sandstones) and Min River outwash plains of Sichuan. Culinary dynamos have been the cities of Changsha in Hunan; Zhongqing and Chengdu in the Red Basin of central Sichuan, named from its red sandstones; and, to a lesser extent, Kunming in Yunnan. These areas have long been united by trade and communication. In addition, they have long-established ties to the north; the passes from Sichuan to Shaanxi have been major communication corridors for thousands of years.

The core of Sichuan was, in ancient times, the independent state of Shu, and Hunan was part of the great state of Chu. Chu, whose population probably spoke largely Thai languages, was one of the most powerful of the Warring States. Under the Han dynasty it retained considerable local authority for a long time. Han tombs reveal foods much like those of later periods; rice, wheat products, vegetables, and a stunning variety of fruits and nuts were eaten. Yunnan entered history as the ancient state of Tian, probably a Tibeto-Burman polity, which had a culture tied to both China and southeast Asia. Later, much of what is now Yunnan was the independent kingdom of Nanzhao, a non-Chinese state with Thai and Tibeto-Burman inhabitants. Nanzhao reached a peak during the Tang dynasty. Today, Yunnan is China's most ethnically diverse province, with almost forty minority groups; their languages belong to at least four totally unrelated phyla. Most of these groups have simple cuisines, based on grain and local vegetables, but the Thai-speaking peoples of the far south have complex dishes very similar to those of north Thailand.

Sichuan's population was reduced by perhaps as much as 75 percent in the violent period between the Ming and Qing dynasties, and was repopulated largely from Hunan and neighboring areas, resulting in a great culinary similarity between Hunan and Sichuan. Yunnan in turn received many of its Chinese inhabitants from

Sichuan, but they adapted to local conditions and were influenced by non-Han nationalities, and Yunnan cuisine remains rather distinctive.

Agriculture is intensive throughout the region, especially in Hunan and Sichuan. Much of the Red Basin and nearby mountain land is terraced. Heavy use of fertilizer and compost has long been typical. Sophisticated irrigation works are typical. The Min River irrigation scheme, designed by the Li family of engineers in the third century B.C.E., is still in use, being one of the oldest (and most sophisticated) irrigation systems still in use.

Historically, this was millet and rice country, with wheat important in the northern fringes. Rice is intensively cultivated in the Yangzi drainage. Locally, in areas too high and rough for rice, buckwheat becomes important; it was traditionally the staple of the Yi nationality of the Liangshan Mountains in Sichuan.

The area has long been a recipient of new crops from outside. In medieval times, Near Eastern foods such as broad beans, sesame, and walnuts became important. Since New World food crops entered China, the extent of maize, white potatoes, and sweet potatoes has exploded in the region. Maize in particular proved ideal for the climate, and quickly replaced millet. (It is often called “Sichuan millet”—*Shu shu*, using the ancient name for Sichuan.) Unfortunately, maize is a heavy feeder and a poor protector of the soil, and its cultivation has led to considerable deforestation and erosion. White potatoes, introduced apparently by Catholic missionaries, do better at higher elevations, and are more important in this region than in most of China. Soybeans do only moderately well, and so were supplemented by broad beans, which entered from the Near East in early medieval times. Later, with the New World food crops, lima beans came to the region; they are locally very important in Yunnan. A variety of fermented bean products is prepared, as elsewhere in China, but this region is distinctive for the common use of broad beans in these, and for the enormous amounts of chili peppers in many fermented sauces. Distinctive, high-quality types of pickled and salted vegetables, particularly garlic, Chinese cabbages, and bamboo shoots, are typical of Sichuan, and are widely exported. The final characteristic flavor element of Sichuan cooking is dried tangerine peel, which is most often found in mixed stir-fried dishes with relatively rich, complex sauces.

The region is even more pig-dependent than other parts of China. Pork is overwhelmingly the major meat. Yunnan produces hams generally regarded as the finest in China, being quite similar to the mountain (*serrano*) hams of Spain; the quality of such hams owes much to their production in cool, dry montane regions. Some minority groups of Yunnan produce a cured pig product consisting of a whole fat hog with the flesh, bones, and intestines removed, leaving only the fat in the skin, which

is then sewn up. The pig wind-cures in the high, cool mountain air.

Chickens and ducks abound. Fish are found only in rivers and lakes, being abundant in Hunan but relatively less so elsewhere. Sheep and goats are raised. Cows and buffaloes are traction animals, but rare as food. Yogurt is made and consumed by Han Chinese (and some minorities) in Yunnan—a rare case of traditional consumption of dairy products by Han people. The custom probably spread from India via Tibet in medieval times. Mixed herds of livestock are, of course, common on the Tibetan plateau (including all west Sichuan), and dairy products are standard fare there.

Salt is produced from salt springs and wells. Drilling very deep salt wells has been an important and profitable industry in Sichuan for two millennia. Unlike sea salt, this salt lacks iodine, as does most food in these mountainous regions; goiter was thus common in historic times, and was known to be associated with eating local salt as opposed to sea salt.

West Chinese food is shaped by geography as well as history and communication. In stereotype, and indeed in reality, the cuisine is distinguished by two things: its use of mountain products, and its hot spicing. China's wettest and most biologically diverse areas occur in this mountainous region. Dense forests, the most diverse outside the wet tropics, provide a variety of mushrooms and fungi. Many species can be seen at a typical street market. Also abundant are bamboo shoots, herbs, and other wild plant foods.
